Impact Analysis of the Niyol Wind Farm on Surrounding Rural Residential and Agricultural land Values in Logan County Colorado

Report Summary

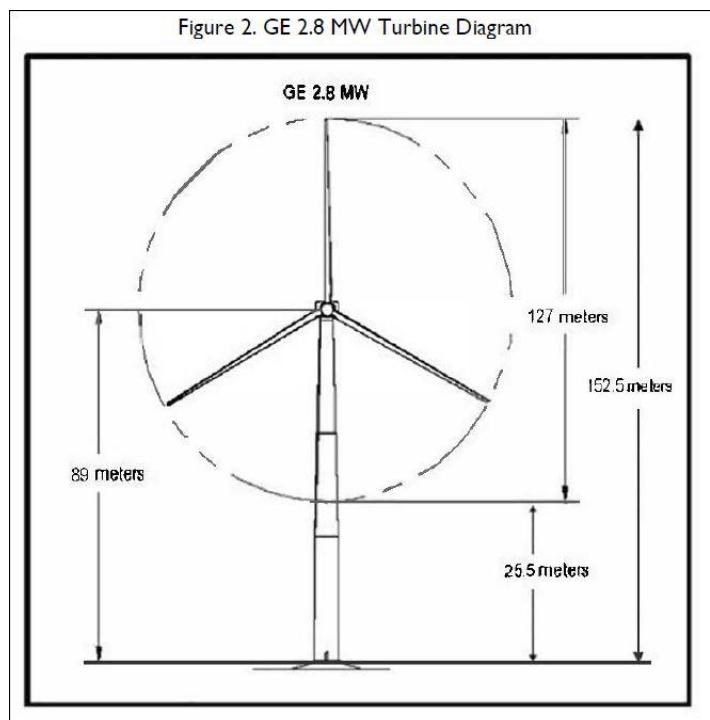

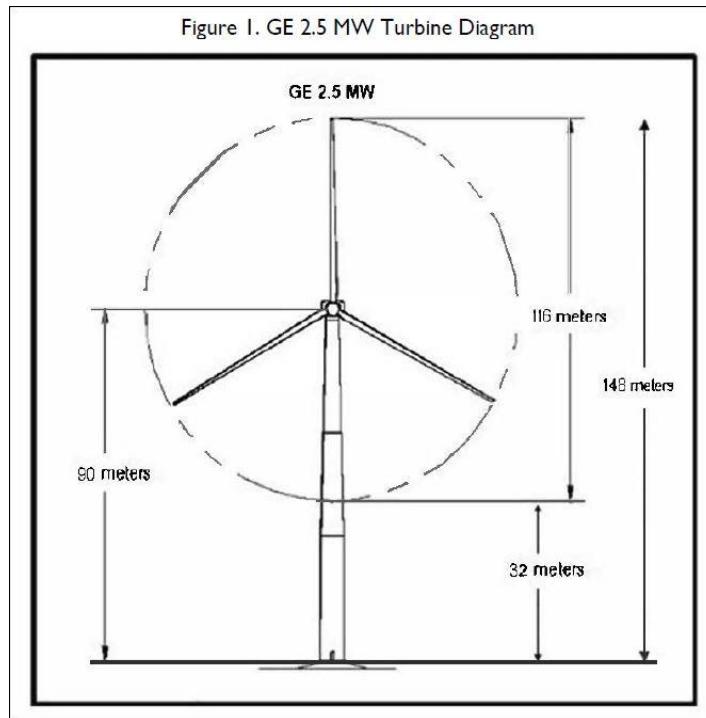

This report was contracted by Concerned Citizens for a Safe Logan County for our opinion on how the Niyol Wind LLC will impact rural residential and agricultural farm values within the wind farm footprint and 1-mile outside of this zone of this proposed wind farm.

Proposed Wind Farm

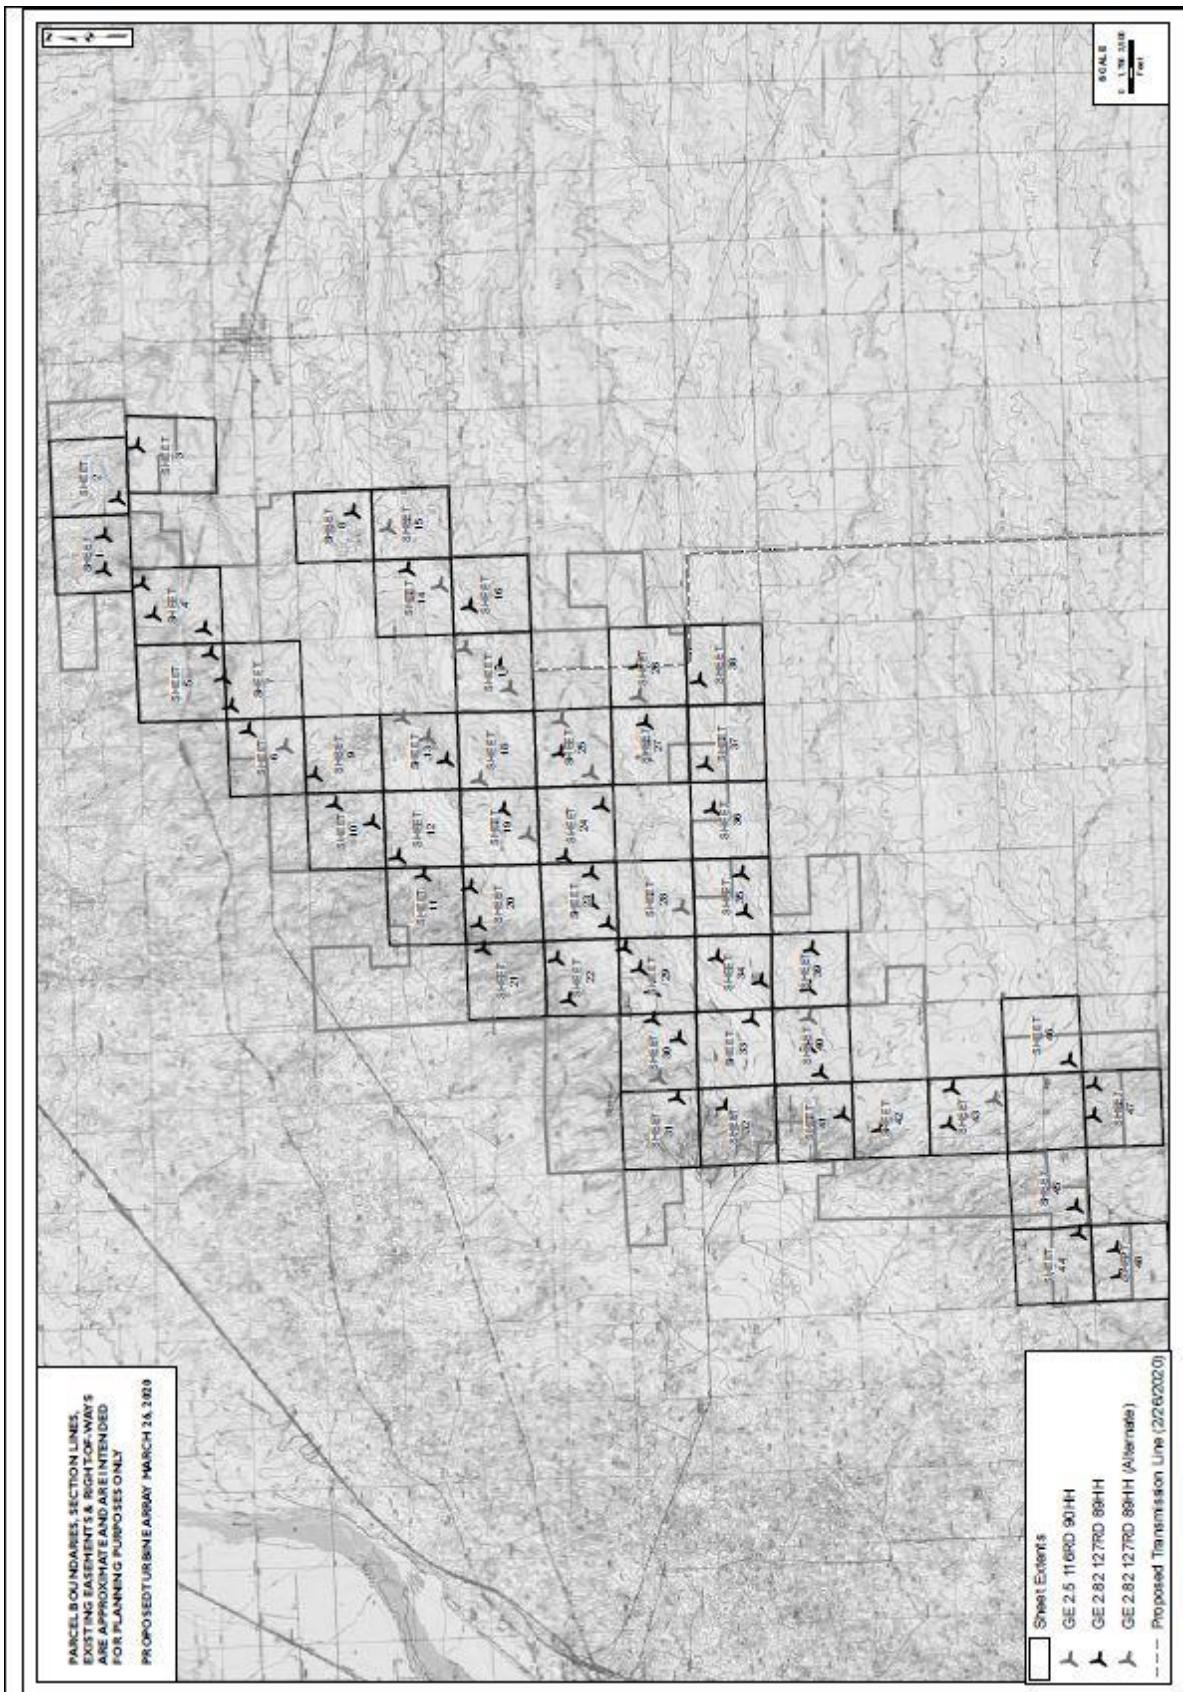

The proposed 200.8MW wind farm is called the Niyol Wind LLC. The developer is Niyol Wind, LLC, which is a wholly owned subsidiary of NextEra Energy, a Delaware Corporation (700 Universe Boulevard, Juno Beach, Florida). The wind farm is located in the Fleming area, Logan County, Colorado. The conditional use permit submitted by Niyol states that the wind farm will occupy 39,314 acres of area. The development will have 89 wind turbines, having a height (including the tower and blades at 12 o'clock position) of 495ft -505ft. The project will include graveled access roads over private land to the wind turbines, a maintenance area of approximately 4-acres, a substation of 10-acres graveled with a chain-link security fence and outside yard lighting, two meteorological towers being 275ft in height, underground and above ground electrical supply lines and a thirty-one mile 230kV high voltage transmission line that is to link up with an existing high voltage transmission line for transmission of the produced energy.

The three-blade wind turbines will be one of two models: the GE 2.5MW turbine or the GE 2.8MW

Turbine. Their designs follow.

The electrical collector lines are to be buried, the collector substation is above ground and connected to an overhead 230kV high voltage transmission line. The map on the next page illustrates the wind farm project.

Format of Study

The format of the study is in three parts. The first part is a qualitative analysis. The second is a quantitative analysis. The third is to apply the qualitative and quantitative conclusions to the subject properties.

A *qualitative* analysis is an analysis that is focused on non-empirical data to guide a conclusion of value. An example would be an observation that a home has better landscaping than another. Another example would be opinion surveys. Application of this type of analysis is helpful in forming a “yes/no” answer to the question “Does proximity to wind turbines negatively impact property value?”

A *quantitative* analysis is an analysis that is focused on empirical or measurable data to guide a conclusion of value. An example would be a matched pair comparison of a sale of a property influenced by a wind turbine as compared to one that is not. The difference in value is measurable. Another example would be a regression analysis whereas the sale price of several “influenced” properties would be compared to the several “non-influenced” properties. Again, a measurable event.

The advantage of using both methods is that they have a symbiotic relationship and help give a full picture of both the motivations and results of such motivations by the buying public to a particular issue. In this case, the presence of a wind farm.

The first part is a literature study to discover what the buying public is reading, viewing and learning through various communication platforms regarding wind farms and land use which would impact their opinion of value. This is a *qualitative* analysis of the impact on property value. The literature study was broad in scope focusing mostly on North America but including other developed nations. We did this for two reasons. First, the typical buyer of properties that would be impacted by wind farms develop their perception of property value and its use from not only their own observations but observations of others. Though these buyers will be from the United States they are sophisticated to understand that the impacts of wind farms are not a locale geographic issue. Second, these same buyers understand the wind turbines being utilized in other developed countries are the same or similar to the ones utilized in the United States, therefore the impacts would be similar.

The second part is a summary of wind farm value impact studies that are applicable to this analysis. This is a quantitative analysis of the impact on property value. The impact studies that were reviewed include both published and unpublished studies, large and small in scope. These studies tend to counter the utility corporate sponsored studies and need to be included as they give insight to the potential impacts that wind farms have on property value.

The third part is to apply the qualitative and quantitative studies to the rural residential and agricultural property values within the Niyol wind farm footprint and also a 1-mile perimeter outside of the wind farm.

Results of Study

The study results are summarized as follows.

Literature Study	<p>The media generally portrays the impact of wind turbines on residential properties as negative, bringing up fear factors and conflicting benefit, or no benefit issues. Overall, the qualitative factor is centered along the lines of health, noise, flicker, and viewshed. With regard to the question, "Do wind turbines affect property value?" the two Centerville Township (Michigan) officials summed it up with this statement: "It is totally counter-intuitive to suggest anything else."</p>
Impact Studies	<p>Wind industry and government supported studies found little to no evidence of an impact. However, independent studies found a significant impact using a variety of valuation methods from paired sales analysis to multi-regression analysis.</p> <p>The Landsink (Ontario, CA) study found a loss range of -8.85% to -50%, with a loss average of -39% for residential homes within 664ft to 2,531ft of a wind farm.</p> <p>The Appraisal Group One Wisconsin Study found a typical loss of 1-10 acre residential lots within ½-mile of wind turbines to be -19% to -40%.</p> <p>The Clarkson University upstate New York study of both residential and agricultural properties found a loss ranging from -15.6% to -31% within 1-3 miles of a wind farm.</p> <p>The Forensic Appraisal Coral Springs (WY) study of large residential lots (35 acres) which would be abutting a proposed wind farm suffered a value impact of -25% to -44%.</p> <p>The McCann study (IL) of residential properties found an average impact of -25% within 2-miles of a wind farm.</p> <p>The Forensic Appraisal Big Sky (IL) study found a loss range of -12% to -25% of residences within 0.31mi to 1.72mi of a wind turbine, with an average impact of -19% at an average distance of 0.65 miles to a wind turbine.</p> <p>The Twin Grove II Wind Farm (McLean County, IL) study of a 198MW wind farm comprised of 120 turbines being 397ft in height over an 11,000 acres area. A paired sales analysis of residential property within the influence of the wind farm found the improved property is negatively impacted by the presence</p>

	<p>of wind turbines. The impact measured ranged from -46.6% to -7.7%, with the higher impact closest to the wind turbines and the impact diminishing as the distance is increased. The distances measured ranged 1,483ft to 5,481ft away from a residence.</p> <p>The Twin Grove II Wind Farm also found an overall impact of -6.63% to -8.5% for vacant agricultural properties within the wind farm zone.</p>
--	---

Application of Studies to the Niyol Wind Farm

The quantitative analysis provided by the studies and qualitative analysis provided by the literature review submitted in this report show two different stories.

One story is that there is no impact on property value due to the presence of wind turbines regardless of the distance to the property. The authors of this position tend to be academicians using statistical analysis. This story is difficult to accept for if we were to take it at face value, we would have to conclude that viewsheds do not matter (Hoen et al refutes that position in their discussion of viewsheds) and no distance to a wind turbine is too close. Comments from Realtors through surveys, testimony, and letters refute that notion. Logic would also question that position. A survey of experienced appraisers who attended the Appraisal Institute webinar Wind Turbine Effects on Value (March 2015, Hoen & Jackson)¹ overwhelmingly stated that they believe wind turbines negatively impact property value. To add to the disbelief of the “no impact” position is that the wind farm developers consistently refuse to “guarantee” that there will be no property loss or purchase the properties from property owners who desire to leave the area due to the development. If the wind developers believed these studies, there would be no risk in taking such a position and it would effectively negate opposition. (As a side note, electrical transmission line developers in Minnesota must buy any property that is encumbered with a new electric transmission if the property owner claims the “buy the farm” provision. So, though rare, there is a precedent of energy developers buying properties that are impacted, or thought to be impacted, by their development.)

The other story is that there is a measurable negative impact on property value due to the presence of wind turbines and that this impact is in direct relation to the distance and viewshed of the turbines. The authors of this position are dominated by real estate appraisers and realtors, often utilizing comparative sales analysis as their method of study. The results of these studies (and others completed by some academicians) have cited losses from 10% to over 50% depending on the distance and viewshed factors. Additionally, they have concluded that these losses are found to begin at the wind farm announcement stage leading to the post-construction stage.

Agricultural land also is impacted by the presence of a wind farm losing -6.3% to -8.5% of its overall value if located within a wind farm.

It is concluded that the qualitative and quantitative evidence supports the position that the presence of

¹ *Wind Turbine Effects on Value*. Appraisal Institute, Chicago. March 5, 2015. Ben Hoen and Thomas Jackson, Ph.D., were the presenters.

wind turbines in close proximity to properties will have a negative impact on property value and this impact is permanent. And, the closer the properties are to the wind turbines the greater the impact.

We conclude that the following impacts will be experienced by the Niyol wind farm on the client's properties:

Properties within the Wind Farm Footprint= -35% impact on property value

Properties 1-Mile outside of the Wind Farm Footprint = -22% impact on property value

Agricultural Properties within the Wind Farm Footprint= -8.5% impact on property value

Application of these estimated losses to the client's property value is:

Niyol Wind Farm Loss to Property Value Estimate			
	total assessed value	impact	value loss
Properties within the Footprint	\$4,014,430	-35%	-\$1,405,051
Properties 1-mile outside of the Footprint	\$6,948,960	-22%	-\$1,528,771
Total			-\$2,933,822

Sincerely,

Kurt C. Kielisch, ASA, SR/WA, R/W-AC

Literature Study

Perception=Value

It is important to remember “perception drives value.” This may appear to be an overly simplistic statement, but what a buyer believes a property is worth and how a buyer acts based on that belief, are truly the core elements of market value. Therefore, to understand market value, appraisers need to examine its driving element – perception. Perception is strongly influenced by the media which is no longer limited to the traditional print, radio, and television venues, but also includes the Internet. The Internet brings opinions, facts, and stories from all over the nation and the world, influencing one’s perception. This perception need not be based on fact; it simply has to be believed and then acted upon to result in an impact.

Some argue that perception is simply revealed by comparable sales. It is true that the resultant action of perception is quantified in the sale, but it may not be true that the underlying perception driving that action is defined by the sale. In appraisal, we call this the *qualitative factor*. Often this factor is identified in appraisal analysis as a judgment call based on perception such as “fair” in a quality description or “undesirable” as to a view. To achieve this perception, the appraiser needs to look deeper into the driving force of the action by reviewing what is being said in the media regarding the question: “Do wind turbines affect property value?” Such a study may be useful to an appraiser to put a qualitative value on this perception when estimating the impact that a Wind Farm may have on property value.

Following is a summary of our findings from published sources outside of the trade industry to get a measure of the public’s perception of wind turbines and their potential impact on property value.

Health Issues

Many people living near operating wind turbines are reporting neurological and physiological disorders that are only resolved when the turbines are off, or when they leave the area. Common symptoms include sleep problems, headaches, dizziness, unsteadiness and nausea, exhaustion, anxiety, anger, irritability and depression, problems concentrating and learning, and Tinnitus (ringing in the ears).² Symptoms can be experienced up to 1.2 miles away in rolling terrain; 1.5 miles away in valleys; and 1.9 miles away in mountainous regions.³ These symptoms are commonly being referred to as “Wind Tower Syndrome”⁴ in the U.S., but they are the same symptoms of a proven ailment, Vibroacoustic Disease (VAD).⁵

In 2007, two Portuguese scientists found that the amount of infrasound and low-frequency noise (LFN)

2 Nina Pierpont, MD, PhD, *Wind Turbine Syndrome: Testimony Before the New York State Legislature Energy Committee*. March 7, 2006.

3 Ibid.

4 Ibid.

5 Mariana Alves-Pereira, Nuno A. A. Castelo Branco, *Second International Meeting on Wind Turbine Noise*. Lyon, France – September 20-21, 2007.

generated by wind turbines is conducive to VAD.⁶ Symptoms include slight mood swings, indigestion, heartburn, mouth/throat infections, bronchitis, chest pain, definite mood swings, back pain, fatigue, skin infections (fungal, viral, and parasitic), inflammation of stomach lining, pain and blood in the urine, conjunctivitis, allergies, psychiatric disturbances, hemorrhages (nasal, digestive, conjunctive mucosa) varicose veins, hemorrhoids, duodenal ulcers, spastic colitis, decrease in visual acuity, headaches, severe joint pain, intense muscular pain, and neurological disturbances.⁷

Besides noise, wind farms can electrically pollute their surroundings.⁸ A study of before-and-after sound waveforms demonstrates how overexposure to high frequencies can cause symptoms such as ringing in the ears, headaches, sleeplessness, dangerously high blood pressure, heart palpitations, itching in the ears, eye-watering, earaches, and chest pressure. All are symptoms of Radio Wave Sickness – a proven phenomenon that predates Wind Tower Syndrome. It takes very little exposure to start experiencing these symptoms.⁹

The symptoms became so bad that four families had to abandon their homes near the wind farms – prompting the wind company to bury the collector line for turbines near the worst-hit homes. They also put an insulator between the neutral line and the grounding grid. It reduced the high frequencies but didn't completely resolve the situation.¹⁰

In 2009, Minnesota's Department of Health released a study on the public health impact of wind turbines. They found that wind turbines generate a broad spectrum of low-intensity (frequency) noise. Though homes typically block most high-frequency noise, they do little to weaken low-frequency noise. Sleeplessness and headaches are the most common health complaints associated with proximity to turbines and are highly correlated with annoyance complaints. Most available evidence suggests that reported health effects are related to audible low-frequency noise. LFN is typically a non-issue at more than a half mile. However, differences in terrain or different wind conditions could cause the sound to reach further. Unlike LFN, shadow flicker can affect people outdoors and indoors. They recommend the following: further testing to determine the LFN impact; evaluating potential impacts from shadow flicker and visibility; estimating the cumulative noise impacts of all wind turbines.¹¹

Although acousticians and engineers working for the wind energy industry conclude that audible noise and low-frequency noise from wind turbines are unlikely to cause health effects, experts in biomedical research have drawn different conclusions.¹²

Industry advocates commonly quote the WHO Community Noise Paper of 1995 which says, "There is no reliable evidence that infrasound below the hearing threshold produces physiological or psychological

effects.” However, the final WHO document of 1999 reversed that statement: “The evidence on low-frequency noise is sufficiently strong to warrant immediate concern.”¹³

A British study surveyed 39 residents already known to be suffering from problems they felt were due to their close proximity to the turbines. On average, 75% of them reported fatigue, lack of sleep, and headaches. Half reported stress and anxiety, and a quarter reported migraines, depression, and tinnitus.¹⁴

It is clearly evident that there are people living near turbines who are genuinely suffering from health effects from the noise produced by wind turbines¹⁵ – despite developers’ and some acousticians’ claims to the contrary.

Field studies performed among people living in the vicinity of wind turbines showed that there is a correlation between sound pressure levels and annoyance, but that annoyance is also influenced by other factors such as attitude to wind turbines and the landscape. However, noise annoyance from wind turbines was found at lower sound pressure levels than in studies of annoyance from road traffic noise. This is because the absolute noise level is less important than the character of the noise produced.¹⁶

People are “in an extremely delicate state of equilibrium with the sonic environment and any profound disturbance of this system will have profound ramification to the individual.” Our auditory and cerebral systems are extremely complex. Thus, issues surrounding noise annoyance/disturbance and associated health effects are not simple. The noise produced from wind turbines is extremely complex...and it is the complexity of the noise and vibration which causes the disturbance.¹⁷

Low-frequency noise is also produced by wind turbines. It’s mainly the result of the displacement of air by a blade and of turbulence at the blade surface. LFNs contribute to the overall audible noise but also produce a seismic characteristic which is why people can say they can “feel” the noise.¹⁸

Body vibration exposure at seemingly low frequencies from 1-20 Hz can have the following effects:¹⁹

- General feeling of discomfort	4-9 Hz
- Head symptoms	13-20 Hz
- Influence on speech	13-20 Hz
- Lump in throat	12-16 Hz
- Chest pains	5-7 Hz
- Abdominal pains	4-10 Hz
- Urge to urinate	10-18 Hz
- Influence on breathing	4-8 Hz

15 Ibid.

16 Ibid.

17 Ibid.

18 Ibid.

19 Ibid.

Over time, symptoms from LFN can have serious adverse physiological effects.²⁰

- After 1-4 years: slight mood swings, indigestion, heartburn, mouth/throat infections, and bronchitis.
- After 4-10 years: chest pain, definite mood swings, back pain, fatigue, skin infections, inflammation of stomach lining, pain and blood in urine, conjunctivitis, and allergies.
- After 10 years: psychiatric disturbances, hemorrhages, varicose veins, hemorrhoids, duodenal ulcers, spastic colitis, blindness, headaches, severe joint pain, intense muscular pain, and neurological disturbances.

LFN intensity is subject to the sudden variation in air flow. LFN also modulates well-audible, higher frequency sounds and thus can create periodic sound. The effect is stronger at night – sometimes up to 15-18dBs higher – because of atmospheric differences. Multiple turbines can interact with each other to multiply the effect – which will be greater for larger, more modern turbines.²¹

Because the wind is inconsistent, so too will be the noise (and thus health effects) caused by wind turbines.²²

Noise and “flicker” at nearby residences often affect the occupant’s health.²³

One particular case has generated substantial press. The d’Entermont family home is in the midst of a 17-turbine wind farm. Soon after the turbines began operating, they started feeling irritation that caused noticeable shifts in their six children’s behavior. They started hearing ringing in the ears, loss of concentration, and high blood pressure. They had to move 30 miles away to resolve the health issues, and no one will buy their home.²⁴

However, these symptoms don’t affect everyone. As a result, the wind energy industry ignores such health claims by leaning on acoustics consultants who base their conclusions on engineering principles instead of on audiologists and physicians who study the effect of sound and vibration on people.²⁵

Likewise, many environmentalists dismiss any health effects – claiming they’re fictitious beliefs fueled by not-in-my-backyard-ism.²⁶

The French National Academy of Medicine has warned that the harmful effects of sound related to wind turbines are insufficiently assessed. They consider wind turbines to be industrial installations and to comply by that fact to specific regulations that take account of the harmful effects of sound as particularly

produced by these structures.²⁷

Health Solutions

The international community recommends generous setbacks be given to property owners from wind farms in order to mitigate any potential health effects and loss of property values. The setbacks range from a minimal 1,500-foot setback²⁸ to 1.5 miles away from any home, school, or business.²⁹ Because symptoms can be suffered up to a mile from the wind farm, one study suggests that turbines should be no closer than 1.5 miles from a residence.³⁰ Some recommend an immediate and mandatory minimum buffer of 2km between a dwelling and an industrial wind turbine and with greater separation from a dwelling for a wind turbine with greater than 2MW installed capacity.³¹

One solution is to filter inverters at each turbine; bury all collector lines; filter the power at the substation before going to the grid, and install a proper neutral system to handle the high-frequency return current.³²

Local governments are advised to establish beyond reasonable doubt that the families' right to respect for their homes and their private lives is not violated. If the State decides that the public interest in building wind turbines is greater than the individual private interest, then the violation is not proportionate without compensation for the individual.³³

Wind Turbine Hazards

Turbines, like all machines, have weaknesses and are subject to accidents and failure. Inclement weather and strong gusts can snap off wind tower blades;³⁴ ice can build up on the blades, break, and throw large ice chunks³⁵ and fling ice shards onto nearby homes,^{36,37} potentially harming nearby residents;³⁸

turbulent wind can accelerate a blade's deterioration, weakening it to the point of breaking off and crashing into nearby homes;³⁹ high winds can also overpower its automatic braking system and result in structural failure;⁴⁰ automatic shut-down systems can malfunction, damaging the turbine to the point of collapse;⁴¹ and gale force winds can shut down turbines and make them a safety concern. In one such case, British police cordoned off a 1,500-foot area around the wind farm for "safety precautions."⁴² Other common problems include fires and blade disintegration caused by mechanical failures and lightning.⁴³

In Europe, which has long had wind farms, turbines are seeing a spike in accidents, defects, and needed repairs. A turbine's gearbox is expected to last 5 years and often quits before then. Due to the huge demand for turbines, manufacturers have no time to test their product before sending it into the field. This demand has so strained manufacturing capabilities that the waiting list for replacement parts can sometimes top 18 months – leaving the turbine motionless the whole time.⁴⁴

Wind farms interfere with weather radar by sending false storm signals,⁴⁵ thus limiting the ability of surrounding areas to know if they should seek shelter or not. They also interfere with military radar, affecting military readiness.⁴⁶ And they may interfere with civilian radar,⁴⁷ making it very dangerous to site turbines near airports or military installations.⁴⁸

Despite the constant warning lights on top of each turbine, wind farms are dangerous to planes. A distance of 1,200 feet is still too close to an airport or landing strip because it's impossible for aircraft to turn fast enough to avoid the turbines. Also, turbines create a downdraft – additional turbulence that pilots have to overcome in takeoffs and landing.⁴⁹

Wind farms can also constitute a nuisance to nearby landowners. Even though the State Public Service Commission approved the facility, such approval did not overrule the common law of nuisance. Accepted causes of nuisance include noise, eyesore, flicker, and strobe effect of light reflecting from blades, potential danger from broken blades, ice throws, and reduced property values.⁵⁰

Conservation Concerns

Even conservation groups are divided on Wind Energy. In North Carolina, environmentalists are fighting over siting issues. Some environmentalists and the wind companies want to place turbines on mountain ridges for optimal winds. But other environmentalists want them off the ridges in order to protect the mountains' natural beauty.⁵¹

Conservation groups are concerned about the impact of wind farms on birds. Poor siting has led to bird and bat fatalities.⁵² According to the American Bird Conservancy, wind towers kill 10,000 to 40,000 birds every year. However, this is still much lower than the 100 million window-related bird deaths each year.⁵³ Bats, however, are killed three times as much as birds by wind turbines.⁵⁴ And many bats killed by turbines are most likely migrating for mating rituals. If such bats are killed then certain bat species are in danger of failing to repopulate.⁵⁵ According to industry advocates, the most damage to wildlife and plant-life happens during construction. After construction, collision consequences are insignificant compared to the effects of other man-made structures, vehicles, and pollution.⁵⁶

Promoters routinely ignore wind development environmental damage. Electricity from the wind is not environmentally benign. Wind plants adversely affect a wide variety of environmental, ecological, and scenic values including bird kills and interference with migration patterns.⁵⁷ And construction disruptions are extensive and turbine installation can significantly affect natural drainage and groundwater.⁵⁸

Property Values and Land Use

Industry advocates say little about a turbine's aesthetic impact. When they do mention property values, they deny that wind farms negatively impact property values. They say property value fears are exaggerated and if they do admit impact, they say the only effect would be more time on the market for sales to be completed.⁵⁹ One utility president went so far as to claim that those who claim property

value diminutions “pull myths out of thin air and persist in wild accusations despite being debunked.”⁶⁰ To prove this point, industry advocates frequently refer to the following studies:

- Relationship between Wind Turbines and Residential Property Values in Massachusetts: A Joint Report of University of Connecticut and Lawrence Berkeley National Laboratory by Carol Atkinson-Palombo and Ben Hoen (2014)
- The Windy City: Property Value Impacts of Wind Turbines in an Urban Setting by Corey Lang, James J. Opaluch, and George Sfinarolakis (2014)
- The Effects of Wind Turbines on Property Values in Ontario: Does Public Perception Match Empirical Evidence? by Richard Vyn and Ryan McCullough (2014)
- The Effect of Wind Development on Local Property Values by the Renewable Energy Policy Project (REPP) (2004)

The 2014 Ben Hoen study analyzed more than 122,000 home sales, between 1998 and 2012, that occurred near the current or future location of 41 turbines in densely populated Massachusetts’ communities. The study determined that wind turbines do not have a negative impact on property values in urban settings. It was an update of his 2009 study. Funding for the study was provided by the Massachusetts Clean Energy Center and the U.S. Department of Energy Wind & Water Power Program within the Office of Energy Efficiency and Renewable Energy.⁶¹

The 2014 Rhode Island study analyzed 48,554 single-family, owner-occupied transactions within five miles of a turbine site, including 3,254 within one mile. The authors concluded that wind turbines have no statistically significant negative impacts on house prices. Funding for the study was provided by Rhode Island’s Office of Energy Resources, University of Rhode Island’s Coastal Institute, and Rhode Island Agricultural Experiment Station.⁶²

In the 2014 study from Vyn and McCullough, the authors analyzed 7,000 home and farm sales in and around Melancthon Township – home to one of Ontario’s first and largest wind farms (113 turbines). They concluded that wind turbine developments have no effect on property values.⁶³

The 2004 study was performed by the Renewable Energy Policy Project (REPP) – an organization dedicated to accelerating the use of renewable energy, reviewed assessed values of property sales within 5 miles of wind projects from 1998-2001 to determine if there was a negative effect on property values within the viewshed of the wind farm projects. In 9 out of their 10 case studies, they found either no change in value or even an increase in value resulting from being in the turbines’ view shed than those outside of it.⁶⁴

64 George Sterzinger (REPP Exec. Dir.), Fredric Beck (REPP Research Manager), Damian Kostiuk (REPP Research & Communications Specialist), *The Effect of Wind Development on Local Property Values*. Prepared for the Renewable Energy Policy Project (REPP), May 2003.

However, the remarkable conclusion that property values increased isn't verified.⁶⁵ They did not follow up with the property purchasers, thus invalidating their conclusion.⁶⁶ The REPP findings surprisingly omit many necessary variables for analysis such as adjustments for a rising or falling market, number of days from listing to sale, residential property vs. rural property, effect of noise, flickering and shadows, distances of the homes from the turbines, and possible change in highest and best use due to the presence of the turbines.⁶⁷ And anyone who has ever owned a home or property knows that assessed values rarely reflect a property's market value.

The study also fails to analyze whether or not the properties had a direct line to the turbines, and they also failed to incorporate distance from the wind farms as a variable. Curiously, the number of property transactions decreases the closer one approaches the wind farm. By only examining change in comparable property values over a three-year period, the study weakens itself because, in most cases, the projects had been announced and debated long before the three-year window opened. As a result, any depressive effect on property values would have occurred prior to the start of the study. The REPP study also did not look at other indices of real estate value, such as rising or falling inventory values, or the number of days from listing to sale.⁶⁸

In reality, close proximity to wind turbines can devalue a property 20-30%.⁶⁹ And even townships widely disregard the REPP study for its wind energy bias, its incomplete data, and its deeply flawed methodology.⁷⁰ ⁷¹

Shortly after the University of Guelph study was published, real estate professionals strongly criticized its findings that wind turbines do not impact nearby property values.⁷² Interviewed professionals shared how wind turbines impact property values:

- “I have had several deals fall apart in this area because, in the appraisal report, it has been mentioned that there are windmills visible or adjacent to the property.”⁷³
- “Turbines complicate your property enjoyment, period. That alone spells depreciated value(s).”⁷⁴

- “If you were to buy your future home, given the choice, would you buy where you would have noise, shadow flicker, an industrial view, potential health issues caused by the turbines, and the possibility of a very difficult resale, or would you spend your money elsewhere?”⁷⁵

Other university-led studies, such as these three published within one year of each other, found different results:

- A 2010 study by Illinois State University used 3,851 residential transactions from January 1, 2001, through December 1, 2009, from McLean and Ford Counties, Illinois to see whether proximity to a 240-turbine wind farm impacts nearby residential property values. They found “some evidence that supports wind farm anticipation stigma theory, and the results strongly reject the existence of wind farm area stigma theory.”⁷⁶
- A 2011 study by Illinois State University looked at sales across a 13-year period to see if the Mendota Hills Wind Farm in Lee County, Illinois impacted the average selling price of nearby residential real estate. The study’s author concludes that it does not. Further, he states that the wind farm significantly increased the selling values of nearby residential properties.⁷⁷
- A 2011 study by Clarkson University looked at 11,369 property transactions over 9 years in Northern New York to see if new wind facilities affected property values. The author found that “nearby wind facilities significantly reduce property values. Decreasing the distance to the nearest turbine to 1-mile results in a decline in price of between 7.73% and 14.87%.”⁷⁸

Industry advocates often liken wind turbines to other man-made structures like water towers.⁷⁹ But water towers don’t move.⁸⁰ If they had no effect, then people would want to live near them. However, developers are balking at even building near wind turbines lest potential buyers of high-end homes be “spooked by the noise and visual distraction of the huge whirling fan blades.”⁸¹

In reality, value comes down to location, location, and location. If an individual is given two identical homes, but one has a wind turbine and the other does not, common sense (and research) shows the house without the turbine will be purchased first. In many cases, there is a complete lack of interest in any homes near existing or planned wind farms. And when they do sell, they usually sell at less than current market value.⁸²

Devaluation also affects what people are willing to pay to rent vacation property near wind farms. In 2017, a choice-experiment was conducted with people who had recently rented a vacation property along the North Carolina coastline to assess the impacts of a utility-scale wind farm on their rental decisions. Visualizations were presented to survey respondents that varied both the number of turbines and their proximity to shore. They found the following:

- No respondents would be willing to pay more to rent a home with turbines in view.
- Many said they would change their vacation destination if wind farms were placed within view.
- A discount of 5% or more was required to attract respondents most amenable to viewing a utility-scale wind farm within eight miles of shore.⁸³

Even when turbines are offshore, seeing them can impact property values. In Henderson, New York, a study of a proposed 31-turbine, 102.3-megawatt project found that the project's 575-foot turbines would be visible from a 15-mile radius, negatively impacting the value of waterfront properties from \$11,300 (low estimate), \$33,200 (central estimate) and \$53,900 (high estimate). The estimates were based on the 15% value depreciation of properties with a view of the nearby Wolfe Island turbines in Ontario, Canada.⁸⁴

When another wind farm was announced in addition to the one at Wolfe Island, waterfront property values started to slide. By the time the additional project was scrapped five years after being announced, waterfront homes were selling up to \$300,000 less than they were before the project. Though buying has started to rebound, properties are being sold for hundreds of thousands below asking price, and properties take years to sell instead of months.⁸⁵

The wind company proposing the Henderson wind farm contested the town's study that estimated a loss of \$40 million in property values. They claim the study used flawed methodology – specifically regarding the distance of the project from the mainland.⁸⁶ If these properties' values dropped, their assessments would too, and homes without a view of the turbines "would probably see an increase in property taxes to make up for the overall drop in property values."⁸⁷

As the Principal of JTC Energy Research Associates wrote for Forbes, "A piece of property, after all, is just what someone is willing to pay for it. Markets are about supply and demand, and all things being equal, why would somebody choose to buy a home with an industrial wind farm nearby? And simply put, it seems impossible to believe that wind turbines would actually add to a property's value."⁸⁸

Assessors are starting to devalue homes that are at least 1,500 feet away from the nearest turbine. In one case, several residents near an industrial wind farm received up to a 10% lower property value due to their proximity to turbines. The assessors considered the turbine space an industrial area and devalued nearby properties accordingly.⁸⁹

In another case, Vermont homeowners living near four wind turbines appealed their assessment due to excessive noise. The local Board of Civil Authority agreed and lowered the assessed value on the \$400,000 home by more than \$50,000.⁹⁰ ⁹¹

In Ontario, property assessments near a wind farm were reduced from -\$101,000 on the low end, to -\$143,000 on the high end.⁹²

In New York, a homeowner appealed his 25-acre property assessment due to neighboring wind turbines. The assessor lowered the assessment by 60%.⁹³

In Vermont, contention arose between landowners and assessors. Landowners said nearby turbines' noise devalued their land, but the assessors rejected their claims. The wind farm developers also resisted their claims on the basis of academic and government studies that showed no impact on property values. However, the Board of Civil Authority reconsidered the claims and reduced the assessments by 8-15%.⁹⁴

Wind farm developers like to promote the idea that while their wind farms may cover a very large area, they only physically occupy 3-5% of the total land area for the towers, associated structures, and access roads. They claim the rest of the land is left largely undisturbed and "available for continued use by the landowner."⁹⁵

However, turbines come with many use restrictions.

Even though a minority may find windmills to be a nuisance, property values can still drop \$2,900 per turbine up to \$16,000 for a property abutting 12 turbines.⁹⁶

In testimony before the Livingston County Zoning Board of Appeals (Illinois) regarding a wind farm, Appraiser Michael McCann shared that properties within 3 miles of wind turbines sell at 25% less

compared to control sales more than 3 miles away.⁹⁷

As with other easements, some claim that the impact from windmills will diminish over time. However, studies from Europe show otherwise. In Germany, which has long had windmills, real estate agents report property value losses between 20-30% for properties in sight of wind farms.⁹⁸

Likewise, Scottish real estate agents found that a 41-turbine wind farm would result in \$1 million in property value losses.⁹⁹

Further, hundreds of homeowners in Scotland fear they have lost vast sums of property value due to nearby turbines. In one example, a cottage lost 50,000 pounds of value because of a planned wind farm half a mile away. Real estate agents are advising sellers to automatically lower their asking price by 30%, but some still can't sell.¹⁰⁰

Another Scottish homeowner put her home on the market after learning of a proposed wind farm less than 500 yards from her residence. After two years, she was unable to find a buyer. One potential buyer withdrew her offer, citing a conversation with the town's planning council that told her the turbines will cause "a whooshing noise and flicker." Her cottage was originally valued at 130,000 pounds before the wind farm, but then the valuation was lowered to 100,000 pounds after it was built. She eventually sold the cottage for 85,000 pounds.¹⁰¹

In the UK, property experts say wind farms can reduce the value of homes by up to 8%.¹⁰²

In England and Wales, a study found that large wind farms (20+ turbines) reduce prices by 12% within 2km. Averaging wind farms of all sizes, the study found the price reduction from wind turbines to be 5-6% within 2km, less than 2% between 2 and 4km. There are small (~2%) increases in neighboring prices where the wind farms are not visible, although these are only statistically significant in the 4-8km area. The author suggests, "These offsetting price effects in neighboring places where wind farms are visible and where they are not may explain, in part, why previous studies that focus only on distance to wind farms fail to find significant effects."¹⁰³

The author further explains, "These findings are comparable to the effects of coal power plants in the US found in Davis (2011) who finds up to 7% reduction within 2 miles (3.2 km). It takes many geographically dispersed wind farms to generate the same power as a single coal (or nuclear) plant, so the aggregate effects of wind farms and the number of households affected by their visual impact is likely to be

considerably larger.”¹⁰⁴

In the UK, a couple successfully sued their conveyancer for “a substantial compensation settlement” for not disclosing plans that a wind farm was to be constructed less than a mile away and that the turbines would be visible from the property. The couple said, had they known about the wind farm, “they would have reconsidered their offer.”¹⁰⁵

In a landmark case, a UK court agreed with a couple that argued that ten 360-foot-tall wind turbines ruined their quality of life. The company responsible for the turbines has to remove them at their expense and pay large fines and legal expenses.¹⁰⁶

The effect of wind farms on property values ultimately “forced” the UK’s Valuation Office Agency to rebrand homes near wind farms into lower tax categories. In one case, a property owner saw the value of their home fall 25% because it is 650 yards from a turbine.¹⁰⁷

In Denmark, so many landowners were concerned about lost property valued due to neighboring wind turbines that a “loss-of-value” clause was passed by their parliament in 2008. It allowed landowners to seek financial compensation for lost property values. Those applicants who received compensation (average of 57,000 kroner per household (~\$7,000) said it “did not come close to reflecting the actual value.” Further, “Estate agents say the amount is often far below the actual property value loss, which in some cases is up to 20 percent.”¹⁰⁸

Property value concerns due to neighboring wind farms are so widespread that property value guarantee agreements are being included in government ordinances nationwide from New York to North Carolina, Illinois, Maine, New Hampshire, and Michigan. For example, voters in the Newfound region of New Hampshire passed wind-related articles by as much as five to one. One of them would require wind developers to guarantee the property value of any home within a 3-mile radius of a wind farm. It deterred the developer of a small 3-turbine operation.¹⁰⁹

The Board of Zoning Appeals in Tipton County (Indiana) approved a conditional use permit for a proposed wind farm with conditions requiring a 1,500-foot setback from property lines and a property value guarantee to “protect non-participating property owners in the project area.” The wind farm company submitted a plan that limited their liability to \$1 million. However, the company is planning on contesting the property value guarantee as a condition.¹¹⁰

Other wind energy companies are resisting such guarantees. For example, the Town of Hammond, New

York, proposed a wind law that requires a wind farm company to compensate property owners who cannot get the appraised value of their home at sale because of the presence of wind turbines. If passed, the company says it will scrap plans to build a proposed wind farm.¹¹¹

In Ontario, Canada, a high court determined that landowners living near “industrial wind turbine projects” do lose property value. The court further accepted that 22% to 55% loss of property values is occurring.¹¹² In a case study of two areas in Ontario with wind turbines, the author concludes, “Real or perceived nuisances resulting from wind turbines produce buyer resistance that results in price diminution” of 22.47% on the low end to 55.18% on the high end.¹¹³ In another case, a member of the Multi-Municipal Wind Turbine group said an assessment of property values confirmed a 25% devaluation due to industrial wind turbines.¹¹⁴ Elsewhere in Canada, landowners in Alberta are opposing plans to build 83 turbines near their properties. To protect their property values, they want the county to implement a 1.5 km setback instead of the proposed 500 meters.¹¹⁵

The effect of wind farms on property values is also a concern in Australia. Rural landholders are worried they may face fewer buyers and devaluations of up to 60% because of neighboring wind farms.¹¹⁶ Elsewhere in Australia, a resident in a community selected for a proposed wind farm said he will sue any of his neighbors who host a turbine on their property because doing so would diminish his property. Lawyers said there was extensive precedent backing his claim of right to damages from turbine noise nuisance.¹¹⁷

The township of Lincoln in Kewaunee, WI performed its own study and found that sales within one mile of the wind farm prior to installation were 104% of the assessed values. Properties selling after the wind farm installation in the same area were at 78% of the assessed value.¹¹⁸ The UK has reported similar impacts up to a 20% loss in value from the presence of four 360-foot tall turbines 550 yards from a new home.¹¹⁹

In some coastal areas with turbines, affluent properties have lost up to a third of their value. However, in rural farming areas, prices remained steady or even increased from the associated income stream from the turbines.¹²⁰

Wisconsin residents fear the impact large wind farms can have on lowered property values. Their fear is justified by a plethora of independent studies and reports that all find the same thing: Wind farms have a

120 Marius Cuming and Lucy Skuthorp, *Wind Farms Change Land Values*. National Rural News (Australia), November 11, 2008.

negative effect on property values.¹²¹

Properties within wind farm areas may experience longer days on market. One study of 600 sales over 3 years within proximity of a windmill found that the days on market were more than double for properties within the windmill zone. The selling price was an average of \$48,000 lower inside the zone than outside. And 11% of homes within the zone did not sell vs. 3% of homes outside the zone.¹²²

At a wind forum held in Grafton, VT, concerned residents discussed the environmental and residential impacts of a proposed wind farm. A representative of a company that specializes in high-end homes and country estates said it was difficult to sell a 40-acre, 5,500 sq. ft. home once the wind project was announced. The property was valued at \$2.2 million but sold for \$1.25 million. The representative said, "People don't come to Vermont to look at wind farms and they don't come to Vermont to hear a lot of noise. So, these are direct impacts on the values."¹²³

Even residents in desert regions are concerned about property values. Residents in a desert region of Nevada popular with retirees and tourists are worried that the installation of 428-feet-tall wind turbines will diminish property values. Residents are familiar with value studies and sound assessments that highlight unforeseen impacts arising from wind turbines near residences.¹²⁴

Wind farms are normally built in rural locations. Therefore, apart from accommodation size, important influences on value will often be the view, the peace and serenity, and a rural environment. In many rural locations, a wind farm will reduce the value of properties located nearby. But as the distance between wind turbines and dwellings increases, the valuation impact is lessened, and the prospect of consequent health problems is reduced. A part of the loss in value will be attributable to the loss of a quality view. However, a substantial apportionment of the loss in value flows directly from the environmental noise pollution and the consequent health impact. A smaller part of the loss will be due to the rotation of the turbine blades, which in certain circumstances will cause strobing light/shadow flicker (which can have health repercussions). In a high-value area of the country, the potential valuation impact is likely to be higher.¹²⁵

In most cases, environmental noise pollution will influence the bulk of property damages. In a well-populated rural area, the cumulative financial damage (the loss imposed on the community) will substantially exceed the public interest that will be served from the wind farm.¹²⁶

Wind farms have significant adverse impacts on environmental, ecological, scenic and property values. The drop in real estate values of neighboring homes is an unfair burden to those who have chosen to live or retire to the country. The value of a farmhouse may be affected by as much as 30% if it is in close

126 Ibid.

proximity to a wind turbine.¹²⁷

One British study of 919 home sales within 5 miles of a wind farm found no impact from wind turbines on property value.¹²⁸ However, the turbines were small. Their maximum height was just over a third (48m) of turbines being currently built. No account was taken of whether the properties concerned had views of the turbines. They lumped all distance zones and rural and town properties into one big pot without differentiating them. There was no before-and-after analysis of sale prices.¹²⁹ Curiously, when interviewing general agents, they found 60% said that proximate wind farms would decrease property values in the viewshed, 67% believe depreciation starts at the planning stages and lessen with time.¹³⁰

The “threat” of a wind farm may have a more significant impact than the actual presence of one. Wind farm developers in the UK are purposely avoiding populated areas in order to mitigate property value-based opposition.¹³¹

Concerned about the impact wind turbines may have on local property values, two members of the Centerville Township in Michigan conducted a literature review of four available studies on the subject. The township committee found that it is reasonable to conclude that the presence of wind turbine generators near residential houses causes property values to decline and further impact on property values depends on location. “This is common sense, and there are no serious scholarly studies that support an opposite conclusion.” Large wind turbines can affect neighboring property values due to noise, health effects, and visual impacts on residents. Some homes have been reported as “not salable” because of WTG proximity. These adverse impacts on property values may not exist in agricultural areas that have huge farms. If the land is being sold as fertile farmland then the presence or absence of a nearby wind turbine is probably irrelevant. If there is a chance that a future wind turbine might be placed on the farmland, a potential buyer might think the land was slightly more valuable. However, though the lessee may slightly benefit, large wind turbines can also affect neighboring property owners who receive nothing because the turbine isn’t on their land. A town real estate agent lost a large vineyard sale within the township because the proposed wind farm was seen as a detriment to potential buyers.¹³²

“The locating of a WTG near a residential house can, at best, have no effect on the value and salability of the house. But logically, as wind turbines are larger and larger, in some cases 400 feet tall, and as they produce constant audible noise over a large area, as they intrude on the viewshed, the only valid conclusion is that nearby residences are less valuable than they would be if there was no turbine nearby. Why would a buyer choose a house within sight and sound of a turbine, if a comparable house at the same

price were available elsewhere, beyond the sight and sound of the turbine? It is totally counter-intuitive to suggest anything else.”¹³³

While some may think a windmill lease on their property boosts their land value, the reality is that they also incur a higher property tax. Their property's appreciation is offset by their neighbors' depreciation. The WTG lessee incurs a higher property tax and receives annual rent for signing the lease/easement. The other landholders find their property values decreased, and they receive nothing.¹³⁴

Though wind energy development may create an income stream, and thus increase a property's production value, that increased production value does not necessarily result in increased market value.

Real Estate brokers in rural areas confirm that property values in wind farm areas are 10-30% less than similar properties outside of wind farm areas.¹³⁵

View adds value to rural property. That's just common sense. Take away the view, and you take away the value.¹³⁶

Homes with a turbine within 300 feet can suffer reduced property values of up to 10%. Noise, blinking lights, glare from the blades, and vibrations all played a role in the devaluation.¹³⁷

In Kewaunee, Wisconsin, a study paid for by a wind farm developer found no measurable differences in home values in the target areas close to the wind farms and the control areas outside of the wind farm vicinity. It found the same for a case study in Mendota, Illinois.¹³⁸

Three years later, The Wisconsin Public Service Commission proposed new regulations that worried Realtors because the setbacks were too small from residences, noise standards were insufficient, and shadow flicker limits were inadequate.¹³⁹ Five years after the PSC's proposal, The Wisconsin Realtors Association asked the state Supreme Court to invalidate a 2009 rule establishing setback requirements for building wind turbines near residential housing. The WRA said 1,250-foot setbacks aren't enough to protect housing values.¹⁴⁰

Vermont's government wants green energy, even if it has to sacrifice its natural beauty to attain it.¹⁴¹ But wind farms negatively impact pastoral beauty, driving tourists away and severely damaging their main

industry.¹⁴² Supporters claim the turbines themselves will become an attraction.¹⁴³ However, empirical evidence worldwide agrees that wind farms tarnish local beauty and damage tourism.¹⁴⁴ Property values will also suffer up to 20% for a turbine 550 meters away.¹⁴⁵ “It is an incursion into the countryside. It ruins the peace.”¹⁴⁶ Real estate agents agree. It’s common sense that an industrial structure will damage what was before a naturally beautiful area.¹⁴⁷ Agents in Britain and Australia and the U.S.A. have found it nearly impossible to sell properties next to wind farms unless they discount it 20-30%.¹⁴⁸ A realtor study around Nantucket Sound found that 49% of realtors expect property values to fall in proximity to a wind farm.¹⁴⁹

Two studies conducted in Nantucket, Massachusetts found that a 130-turbine offshore wind farm would drive enough visitors away to see a loss of up to 2,500 tourism-related jobs. They also found that inland property values would decline 4.6% while the waterfront properties suffer nearly 11% diminution for a total loss of \$8 million in yearly tax revenue.¹⁵⁰

Combining an area of natural beauty with industrial development like a wind farm will have an adverse impact on its desirability. It is not only devalued, but the property may also be rendered unsaleable. Turbines not only have a visual impact, but they also impact the quality of life. People who buy rural land typically do so to enjoy the natural views, but a wind farm within their viewshed ruins the horizon and heritage views.¹⁵¹

The scenic impact of wind plants is significant, and as valued natural landscapes disappear, more concern is apparent.¹⁵²

Another attraction of rural land is the quiet. Buyers want someplace to get away from the noise and sounds of industry and the city. Closing the door [on a wind farm] eliminates the view, but it does not eliminate the sound. The constant drone cannot be escaped. It takes away the enjoyment of their property. It doesn’t allow them to sleep at night.¹⁵³

Their greatest concern is the substantial loss of value of their property. They do not believe they can sell

without substantial loss and cannot afford to sustain the loss and move.¹⁵⁴

Wind farms destroy property value; they take a property of substantial value and take away all of the characteristics that are the strengths of that property. The visual impact takes away value. The noise takes away value. The property owners complain that the wind turbines take away value and there is no way for them to escape.¹⁵⁵

In Maryland, a wind farm developer accidentally proved the diminution of value when he bought two abutting properties to his wind farm and was unable to sell them for their purchase price. He bought one property for \$104,447.50 and sold it for \$65,000. He bought another property for \$101,049.00 and shortly thereafter sold it for only \$20,000.¹⁵⁶

A similar thing happened to a wind farm developer in New York, as explained by the landowner who sold the property to the wind farm company: "In Apex's glossy brochure, the Wyoming County property that's listed as having sold for \$245,000 happens to have been mine. Apex conveniently left out the most important facts about the property: It was a 93-acre farm, sold for \$245,000 on June 11, 2013, prior to completion of the 58-turbine Orangeville wind factory that was being constructed. The new owner subsequently broke up the property into three parcels, two of which were sold off after the turbines went up, in July and August 2014. The combined assessed value of the three parcels is now \$205,000. That's a \$40,000 or nearly 20 percent loss of value after the Orangeville wind factory was built."¹⁵⁷

Values of the natural and scenic properties within one-half mile and probably within a mile of the wind turbines will be negatively impacted. The visual impact and the noise impact will substantially diminish special attributes of property including scenic view, natural setting and peace, and quiet. Undeveloped properties will be rendered undevelopable. Some parcels may be rendered unsaleable. The visual impact beyond a mile will likely adversely impact value. The sound impact will apparently vary outside one mile, but some properties outside one mile will be adversely impacted by the noise.¹⁵⁸

Studies have shown that fear of wind farms can negatively affect purchase prices even if the project is a mile or more away. In one case study, 350 acres of premium ranch land was put on the market for \$2.1 million. A prospective buyer agreed to the sale price but backed out when the seller disclosed a 27-turbine wind farm within a 1½ mile radius from the property. The seller discounted the land by 25%, but the buyer still declined to purchase. After two years, there has been little interest in the property despite its other positive characteristics.¹⁵⁹

Independent studies have shown an average diminution of value up to -37% when the turbine is on the property; up to -26% average diminution for properties within .2 – .4 miles of a turbine; and up to -25% average diminution for properties within 1.8 miles of turbines. Properties can also suffer an additional 15-

25% diminution in value due to infrastructure construction (clearing, blasting, digging, etc.), HVTLS to transport generated electricity, substations, additional traffic for servicing turbines and HVTLS, and additional roads.¹⁶⁰

Wind farms have the potential to impact local property values.¹⁶¹

To calm property owners, one township recommended that the wind farm developer provide property value assurances that are transferable to subsequent owners of the wind facility.¹⁶²

Noise

Industry advocates say that the windy nature of rural locations often masks the quiet nature of modern turbines, even for “the very few individuals” located close enough to hear it.¹⁶³ However, turbine noise greatly affects people even a mile away, and low-frequency noise makes people quite irritable.¹⁶⁴ Industry advocates say little, if anything, about infrasound or low-frequency noise.

The environmental noise pollution from wind turbines built too close to dwellings causes serious discomfort, and often health injury, to families. Oftentimes those affected did not object to the construction, accepting the developer’s assurances that noise would not be problematic.¹⁶⁵

Turbines interact and placement can influence noise emission. Other factors include the constantly changing atmosphere and wind speed, temperature, and terrain. Noise, particularly low-frequency noise, travels not only seismically but also airborne over the terrain. Local geography can sometimes act like a giant microphone.¹⁶⁶

Shadow flicker and noise are detriments. Noise at the turbine hub can range from 100-105 dBA. It can be noticeable for long distances in more remote areas with existing low ambient levels (Humans can differentiate sounds up to 3 dBA above background levels).¹⁶⁷

Quality of Life

Turbine-generated noise has an adverse impact on quality of life and may adversely impact the health of those living nearby. Research links noise to adverse health effects such as sleep deprivation and headaches. Sleep deprivation may lead to physiological effects such as a rise in cortisol levels – a sign of physiologic stress – as well as headaches, mood changes, and inability to concentrate. Initial research into the health impact of wind turbine noise (including the ‘visual noise’ of shadow flicker) reveals similar findings.¹⁶⁸

Even proximity to small wind farms can have a serious impact on nearby residents. One Illinois Township, concerned about the potential effects of a 22-turbine wind farm, surveyed its residents and found that, on average, 42% were bothered by blade flicker and noise, had been awakened by turbine sound, and had TV reception problems. Nearby property owners also cited increased lightning activity, increased traffic hazard, annoyance at the tower’s blinking lights, the emergence of strange symptoms, and fears of EMFs. These tangible and intangible issues had a marked impact on the market value of nearby real estate. Reluctance to live near the turbines dramatically increased with proximity. For example, 41% of residents would not build or buy a home within 2 miles of the turbines. Within a half mile, 61% would not build or buy a home. And a quarter mile away from the turbines, 74% would not build or buy a home.¹⁶⁹

In Oklahoma, a couple is trying to move away from wind turbines because they “can’t get accustomed to the sounds because it’s constantly changing.” Their home near the turbines has sat on the market for two years and has received one offer that was 30% below the appraised value.¹⁷⁰

In Vermont, landowners reported persistent noise from the turbines that “penetrated the house”, causing sleep problems, difficulty with their ears, a pounding sensation in their home, and bothering their children. They abandoned their home but have been unable to sell it, citing disruption from the turbines as the primary reason.¹⁷¹

In Maryland, residents living near wind turbines have filed suits, alleging that the wind farm has interfered with their use, enjoyment, and value of their property. Residents also say that the wind farm has caused mental and physical health problems.¹⁷²

Wind farm developers said property values wouldn’t suffer. But the town zoning administrator did his own empirical research and found that sales within 1 mile of the windmills prior to their construction were 104% the assessed value, and properties selling in the same area after construction were at 78%. Sales more than a mile away were at 105% the assessed value before and 87% after. They also found several properties have taken much longer than normal to sell, and some are still on the market.¹⁷³

173 *Excerpts from the Final Report of the Township of Lincoln Wind Turbine Moratorium Committee*. Prepared by

A New York landowner has a turbine on his property 2,000 feet from his house and says the turbine rattles his windows, and he can hear some turbines a mile away in his house. The wind company said the sound wouldn't exceed the sound of a refrigerator 900 feet away. He was joined by two other neighbors with similar complaints and who also said neighbors to the turbines started experiencing seizures, anxiety attacks, learning disorders, and other ailments once the turbines started running. Neither he nor the other leaseholders, nor the town has received any promised compensation because the turbines are not selling into the grid. They were told the lights would be the softest available but instead were much brighter than any anticipated.¹⁷⁴

Wind turbines produce no constant tonality, making the creation of a noise standard challenging.¹⁷⁵

Audible noise isn't the issue; it's the low-frequency sound waves. 2-3Hz can cause vomiting and other serious health issues. 12Hz can cause hallucinations.¹⁷⁶

Hills and valleys can create a megaphone effect that can focus the direction, combine, and intensify the sounds of multiple turbines.¹⁷⁷

Because of the deep foundations necessary to stabilize large wind turbines, LFN is transmitted down and throughout the contours of the land, often following bedrock, and even accelerates to immerge randomly miles from its origin.¹⁷⁸

500' setbacks are "woefully inadequate...Anything less than a half mile is a recipe for disaster."¹⁷⁹

Audible noises and LFN vibrations should be considered plus the potential noise of a failed bearing.¹⁸⁰

In one case this year, two families in Ontario had to move due to adverse health effects from nearby wind turbines. One of the displaced landowners said he started suffering from very high blood pressure, sore feet, and irritability once the farm was online. Once he leaves the farm, he quickly recovers. The wind company is paying for one of them to stay in a hotel while tests are being done on their property.¹⁸¹

An industry spokesperson said such complaints are "few and far between" and "there's no cause and effect relationship between audible sound produced by turbines and adverse health effects." He even went so far as to claim, "...all research to date indicates that turbines do not produce infrasound at levels near enough to have impacts on humans."¹⁸²

Industry advocates often say health concerns are exaggerations, and those who complain “are just worried about their real estate values.”¹⁸³

Elizabeth May, the former Executive Director of Sierra Club of Canada, vehemently defends wind energy but admits that literature studies show that wind towers negatively affect human health. She makes a concession for better project siting – away from impacted citizens.¹⁸⁴

Strobe lights and shadows destroy any feeling of peace and solitude.¹⁸⁵

The only potential health effect the wind industry acknowledges is toxic or hazardous materials in the form of relatively small amounts of leaking lubricating oils and hydraulic and insulating fluids.¹⁸⁶ However, even small leakages of such materials can negatively impact groundwater if left unchecked over time.¹⁸⁷ Fluid leaks not only drip directly downward, but they also fly off the tips of the spinning blades, thus spreading the contamination over a wider area.¹⁸⁸ On-site storage of new and used lubricants and cleaning fluids also constitutes a hazard.¹⁸⁹ Even the National Wind Coordinating Committee recommends setback requirements to provide “an adequate buffer” between wind generators and consistent public exposure and access.¹⁹⁰

Several case studies by industry advocates show little to no concern for proximity landowners. In Oregon’s Stateline Project, a 127-turbine farm covering 15 square miles in 2001 only sparked concerns over wildlife protection.¹⁹¹

Southwest MN has been building wind farms since 1995 ranging from 17 turbines to 143. Very few issues were raised during the review and permitting process and only after being built have issues emerged regarding poor television reception in proximity to the farms, additional noise generated by loose pieces of material within the blade at low speeds; cleanup of materials associated with turbine or blade modifications. Neighbors have also been complaining of their aesthetic detriment. Bird health is also an issue.¹⁹²

As the number of houses near to, or with a view of the installation increases, the likelihood of aesthetic or economic objections seems to increase.¹⁹³

New homeowners were attracted by the area’s rural character and do not view their land as a source of

livelihood, nor identify with the farmers in the area who earn their living working their land. These “commuter” households are less likely to support a proposed wind project because they do not understand the economic situation of resident farmers and the extent to which wind energy revenues may act as a buffer against the fluctuations of the farm economy. Suburban development pressure may not be a fatal problem if the remaining farmers still control the local government.¹⁹⁴

Developers may wish to consider compensating the community in some fashion that benefits even non-participants, such as impact payments to the township. Resulting benefits, such as reduced property taxes, may help to address concerns about inequities.¹⁹⁵

A rural mountain community in Virginia fears that a proposed 19-turbine, 400-feet-tall-each project will blight their rural landscape and destroy the area's scenic beauty. The wind farm developer claims the turbines can power 20k homes. Community response has been very negative. Residents are afraid the turbines will kill tourism—their only industry—and negatively impact property values.¹⁹⁶

A proposed 67-tower wind farm in Illinois sparked strong opinions among its affected community. Supporters say it will bring additional property tax revenue, jobs, and clean energy. Its opponents say it will be an eyesore, a dangerous obstacle to crop dusters, and would lower property values. An acoustical engineer from Michigan testified that the turbines would create noise that could affect nearby residents.¹⁹⁷

Turbines are visually distracting, out of place, and threaten residents' peace and quality of life.¹⁹⁸

Turbines create infrasound, low-frequency noise, flicker effect, loss of TV reception, cell phone, local networking reception disruptions, and electronic/electromagnetic interference. Careful placement might lessen the effects, but it's doubtful.¹⁹⁹

Strobe lighting from the towers is a source of electrical pollution.²⁰⁰

Turbines generate flicker and shadows that can distract nearby motorists.²⁰¹

They also interfere with television signals, thus affecting the quality of life for nearby residents.²⁰²

In addition to landscape blight, landowners are furious when the wind farm developers bring new transmission lines to transmit the wind energy to metro areas. But utilities are generally dismissive of such

concerns, usually saying that “the importance of the lines outweighs the aesthetic worries.”²⁰³

In pursuing alternative energy sources, it is imperative not to strip property rights to streamline green energy projects as the Ontario Minister of Energy proposes; he wants to invalidate municipal zoning laws preventing industrial wind farms and severely restrict what citizens can appeal. ²⁰⁴

Tall structures are highly visible.²⁰⁵

In Europe, where wind farms have existed and operated for many years, people are loath to be near them, especially in scenic areas.²⁰⁶

Economic Impact

Some townships prefer to look at the projected tax revenues from proposed wind farms. One township in Ohio estimated that a 100MW wind farm would yearly generate the tax dollar equivalent of 449 homes, and they estimate a 300MW farm would generate the tax dollar equivalent of 1,347 homes. Due to conflicting studies on the impact of turbines on property values, they chose to disregard the issue completely. They anticipate significant positive local property tax impacts are possible assuming they can tax and collect at local levels. They expect local spending, job creation, lease payments, and earnings and outputs to increase regardless of the turbines’ tax status. And they expect to maintain a “healthy, equitable and sustainable tax base” by balancing residential development with commercial development and conserving open/farmlands to prevent the county from continuing to become a “bedroom community.”²⁰⁷

Wind farm projects have little to no significant job impact.²⁰⁸ In Ireland, wind energy promoters’ claims of job creation were rebutted by Britain’s environment secretary who said that wind farms had “significant impacts on the rural economy and the rural environment.”²⁰⁹

Wind farms contribute little to county property taxes. In some states, energy producing equipment is exempt from property taxes; taxable items may be limited to foundation and tower structure. Some developers also apply for additional local tax relief.²¹⁰

A public policy research group studied a proposed wind farm in Nantucket Sound and found it failed the cost-benefit test recommended by the U.S. government for assessing large-scale projects. The wind farm developer stressed the value of wind power as a source of clean, renewable energy. But the study found that the overall economic costs of the project would exceed benefits by \$211.8 million. Without \$241 million from state and federal subsidies, the project would not be financially viable. And while the farm may generate some wind energy jobs, the impact on tourism would result in a net loss of 1,000 local jobs.²¹¹

Industry advocates frequently cite additional tax revenues as a positive reason to build wind farms. General Electric, the wind turbine manufacturer that's currently backlogged \$12 billion in turbine orders, claims that over the long-term wind farms will add \$250 million to the US Treasury. However, they also acknowledge they will only begin to "pump money into the US Treasury" once the Production Tax Credits expire. PTCs are good for the first 10 years of a wind farm's production. They also project creating thousands of short-term construction jobs with long-term employment of 1,600 over 20 years or more of operation. They also project 10 million metric tons per year of CO2 emissions avoided.²¹²

Rural tourism is big business in the UK (worth approximately \$26.7 billion) and supports up to 800,000 jobs. 75% of visitors say the quality of the landscape and countryside is the most important factor in choosing a destination. Between 47% and 75% of visitors felt that wind turbines damage landscape quality. Of the three areas they studied, they found that 11% of visitors would avoid Case #1, resulting in a loss of \$48.5 million and the loss of 800 jobs. Approximately 7% of visitors would not return to the second case, resulting in a loss of \$117 million and 1,753 jobs. In the third case, just 5% would stay away, but its affluence would result in \$668.5 million lost along with 15,000 jobs. In some areas, 49% of all sectors of rural businesses experienced a negative impact.²¹³

The success of rural enterprises is inextricably linked to the maintenance and conservation of a healthy and attractive and irreplaceable rural appeal.²¹⁴

In a tourist area of the UK, five wind farms are proposed totaling 71 turbines along 18 miles. In a pilot survey of 1,500 visitors, approximately 95% of the visitors said wind turbines would spoil their enjoyment of the landscape. And this spoiling directly translates into less business from tourism and thus, lost jobs.²¹⁵

In another tourist area in the UK, two-thirds of local businesses said turbines are visually intrusive. While 54% thought wind turbines would increase their 'green' credentials, 27% believed it would still have a negative impact on the tourism industry by reducing visitor numbers. After the details of the tower heights were revealed the next year, the 27% grew to 39% who felt the 400-foot-high turbines would make visitors stop visiting completely.²¹⁶

In North Devon, an area renowned for its beauty, a before-and-after survey was conducted to gauge visitors' feelings toward possible wind farms. Before details of their 300' height were revealed, 34% were generally favorable and 66% unfavorable towards turbines. After the size and location of the turbine proposals were revealed, the number of 'unfavorable' visitors rose to 84%. When asked if wind farms would affect their choice of holiday destination, just less than 50% claimed that they would still choose North Devon. A further 39% said they would choose North Devon, but subject to the size and location of the wind farms. Eleven percent would stay away from North Devon altogether. Visitors claimed that if they found wind turbines on their arrival and had not been previously informed, 15% would complain to their tour or holiday operator and around 28% stated they would never return.²¹⁷

Scotland is also proposing wind farms, but a visitor survey found that 15% of visitors would not return if wind turbines are built, resulting in a potential loss of \$133.7 million and 3,750 jobs.²¹⁸

Wind energy advocates claim their wind farms would actually boost tourism. They tried it in the UK, and both utterly failed, proving that visitors do not accept wind farms as tourist attractions. In 1999, a visitor's center was built in Norfolk, UK – then home to one of the largest turbines in the world. It ran out of money and closed in 2002. Then in 2001, a \$9.1 million visitor center was built with hopes of attracting 150,000 annual visitors to its wind farm. Despite opening with much publicity, it attracted less than a tenth of projected visitors, and it went bankrupt. Its CEO debunked advocates' mindset when he said, "Sadly, just like many eco-attractions, they're not sustainable; there's just not enough interest."²¹⁹ They recommend micro-generation as an acceptable alternative.²²⁰

In summary, the media generally portrays the impact of wind turbines on residential properties as negative, bringing up fear factors and conflicting benefit, or no benefit issues. Overall, the qualitative factor is centered along the lines of health, noise, flicker, and viewshed. With regard to the question, "Do wind turbines affect property value?" the two Centerville Township (Michigan) officials summed it up with this statement: "It is totally counter-intuitive to suggest anything else."

Review of Impact Studies

Review of Impact Studies

Introduction

Though not an exhaustive listing, the following studies, and articles were utilized to develop an opinion as to what impact a wind farm will have on property value.

- *The Impact of Wind Power Projects on Residential Property Values in the United States: A Multi-Site Hedonic Analysis (2009 updated in 2013)* by Berkeley National Laboratory (California).
- *Impact of Industrial Wind Turbines on Residential Property Assessment in Ontario, 2012 Assessment Base Year Summary* by Municipal Property Assessment Corporation (MPAC).
- *Case Study Diminution in Value Wind Turbine Analysis (2012)* by Ben Lansink, AACI, P.Appr, MRCS, real estate appraiser (Ontario, Canada).
- A market study by Glen Taylor on the Chevron Wind Tower Development in Wyoming.
- *Wind Turbine Impact Study (2009)* completed by Kurt C. Kielisch, Appraisal Group One (Wisconsin).
- *Values in the Wind: A Hedonic Analysis of Wind Power Facilities (2011)* completed by Heintzelman and Tuttle, Clarkson University (New York).
- *Coral Springs Development Study (2007)* completed by Kurt C. Kielisch, Appraisal Group One (Wisconsin).
- *Mendota Hills Residential Property Impact Study (2011) completed by Michael S. McCann (Illinois).*
- *Big Sky Wind Farm Matched Pair Analysis Study (2015)*, completed by Kurt C. Kielisch, Forensic Appraisal Group (Wisconsin).

The following is a review and critique of each study.

Berkeley National Laboratory Study

In the fall of 2009, the Berkeley National Laboratory (California) released their study, “The Impact of Wind Power Projects on Residential Property Values in the United States: A Multi-Site Hedonic Analysis.” This study was sponsored by the Department of Energy. In summary, this study found no relationship between the presence of wind turbines and residential property value. A review of this study brings out several observations that the reader should be cognitive of when considering applying these findings to a wind farm in Illinois.

No Real Estate Value Experts

The first problem with this study is the use of hedonic modeling to isolate variables in value. Though this is a recognized methodology in the statistical world; it is still young in its application to the real estate appraisal field. This modeling technique is considered a tool in the appraiser’s toolbox which can assist him in making valuation decisions, but it is not the sole source of determining value in real estate. The appraiser must also apply his expertise and, some would say, “art,” to the understanding of the valuation process to arrive at a realistic interpretation of the results of the study. This fact is recognized in the study where it states, “It should be emphasized that the hedonic model is not typically designed to appraise properties...”²²¹ One of the leading real estate appraisal texts adds, “Appraisers should recognize the differences between statistical processes in the collection and description of data and should be able to distinguish between descriptive and inferential statistics. Without an understanding of the issues, any use of statistical calculations is dangerous or ill-advised.”²²² It is here where we take issue with the foundation of the study and its authors.

Through correspondence with Ben Hoen, the primary author of the Berkeley Labs study, it was learned that no one involved in the study was an expert in real estate valuation, nor had any practical experience as a real estate appraiser, a real estate broker, or as a real estate developer. Ben Hoen is trained in applied statistics, having a master’s degree in that field. The other signature authors are Thayer, Ph.D. in economics (i.e. how things work, not their value); Sethi, Ph.D. in agriculture and resource economics (again, how it works, not its value); Wiser, Ph.D. in energy and resources; and Cappers, masters in applied economics. In review, one can see that these authors are well-schooled in economics, but not in the practical valuation of real estate. This academic approach most likely led to an error in the selection of the database for the model—the use of improved residential properties.

Use of Improved Residential Properties

The use of improved residential properties in large-scale statistical analysis can be problematic. Appraisers know that the easiest real estate to use in statistical analysis is vacant land. This is due to a number of variables which may impact the value. When valuing land, there are approximately 12 value factors commonly used by appraisers to represent how the market (buyer) would react.²²³ The value factors that are specific to land are:

221 Berkeley study, page x.

222 *The Appraisal of Real Estate* – 12th Edition (Chicago: Appraisal Institute), 440.

223 This number may vary between property types and appraisers, but the noted variables are typical.

- Size
- Location
- Shape
- Topography (woods, open area, soils, physical limitations)
- Water features (ponds, creeks, streams, rivers, lakes, oceans)
- Wetlands and flood zones
- Terrain (level, rolling or severe)
- Zoning
- Utilities (private or municipal water and sewage, natural gas, electrical and telephone)
- Road frontage (town, county, highway or interstate roads)
- Access (direct off-road, indirect via a long driveway, access easement, no access)
- View (including positive and negative environmental factors)²²⁴

When you add residential improvements to the equation you not only have the 12 value factors of land, but you add another 25 variables which typically include:²²⁵

- Location of improvements
- View
- Physical age
- Condition
- Quality of construction
- Style/design/number of stories
- Exterior siding
- Roof cover/gutters/downspouts
- Gross living area above grade
- Basement (full, partial, crawl, exposed/hillside)
- Finished area in basement
- Garage/carport (size, # car storage)
- Finished area in or above garage
- Room count (total rooms/bedrooms/bathrooms)
- Patios (concrete, brick)
- Porches (open, covered, screened)
- Decks (type of wood, size, levels)
- Air conditioning (central, zoned, through wall)
- Type of furnace (forced air, hot water, steam, gas, in floor, fuel oil, electric)
- Energy efficiency items
- Functional utility (layout of interior rooms, functional problems, outdated items)
- Extra buildings (sheds, barns, workshops)

224 These factors are mentioned in *The Appraisal of Real Estate* - 12th Edition (Chicago: Appraisal Institute), 333.

225 This number may vary between property types and appraisers but are typical for most properties.

- Fireplace (wood, gas, stoves)
- Landscaping (including paved/concrete/brick driveways and walks, shrubbery, and gardens)
- Special features (Jacuzzi, hot tubs, built-in appliances, stone countertops, wood or tiled floors, built-in entertainment centers, theater rooms, swimming pools, ponds, fencing, etc)

226

Factors that were not mentioned in this list, but have an influence on value, are street appeal, interior decorating and availability of financing.

As you may imagine, when you add these value factors to the land value factors you have an exponential number of potential match-ups and adjustments. For this reason, an experienced appraiser would know that to compare 7,500 improved properties of all sizes, styles, ages, conditions, gross living areas, amenities, and different localities would be a nearly impossible task without the ability to appraise each sale independently, assessing all the factors of value.

The list of variables considered in the hedonic analysis appears on page 21 of the Berkeley study. You will notice there are only three variables in relation to land, that being size in acres, cul-de-sac, and waterfront (yes/no question with no consideration to quality, type, amount, etc.). In relation to the actual improvements, there are 9 variables. These variables are:

- Age
- Gross living area above grade
- Number of bathrooms
- Exterior siding (only variable is stone, brick or stucco – not vinyl, steel, wood or log)
- Air conditioning (central air only, yes/no)
- Finished basement (only includes finished if it is greater than 50% of area)
- Waterfront (the only factor is fronting on water with no reference to type, size, amount, etc.)
- Condition
- Vista (view)

This list is missing 26 other distinct and important variables of value for a residence. To ignore these is an error and could result in an inaccurate comparison of the sales used in the analysis.

Due to the sheer size of this study and the logistics of obtaining the data on the improved properties, the authors of the study chose to collect their data via government records. These records included assessor records, which can be problematic. Few assessment records are considered up-to-date on the condition of the property and other improvements which give value, such as fencing, landscaping, room layout, and decoration. Most assessment records are only updated on a periodic basis and contain the base information about the residence. This base is what undoubtedly limited the selection of the valuation variables utilized in the hedonic models.

Location of Sales – Urban vs. Rural

An appraiser or real estate professional recognizes that location is of primary importance. In most cases,

226 Note: This is not an inclusive list of the variables present with residential improvements. Many of the items listed are found on the Fannie Mae form 1004/Freddie Mac form 70.

it simply cannot be adequately factored in to get a true representation of how the market would react. For instance, there is a distinct difference between the typical buyer of a rural property, who desires to get away from the noise and congestion of the urban environment and is willing to be inconvenienced to obtain this escape, as compared to that of an urban buyer who will accept the noise, congestion, and other urban settings for the convenience factor. Therefore, it would be unwise to compare residential sales of these separate and distinct environments to each other. However, the Berkeley study does just that.

An example of this may be found on page 84. This page shows a map of the wind towers and the residential sales utilized in the study. The red '+' marks denote the placement of the wind turbines and the maroon dots denote the sales used in the study. This map shows nearly all the sales utilized were in an urban area, either in Kennewick (9 miles to 20 miles away) or Milton-Freewater (approximately 9 miles away). Only a few sales are located outside of these urban areas. An extreme example of this would be found on page 90, whereas nearly all the sales are located in the City of Weatherford. This pattern is repeated in most of the study locations (pages 93, 99, 102, 108, and 111). The best study, having the most non-urban sales, can be found on page 96, whereas only a small portion of sales is found in the cities of Paw and Compton. Unfortunately, this study had only 2 sales that were less than 1.00 mile from a wind turbine out of a total of 412 sales utilized.

Of particular interest was the study found on page 99. This study area is located in the Kewaunee and Door County area of Wisconsin. This author is very familiar with this area, having appraised a number of properties along State Highway 57, which runs through these two counties. In this study; you can see that most of the sales were from the urban centers of Luxemburg, Casco, Brussels, and Algoma. In addition, the Algoma area fronts on Lake Michigan with dynamic views of the lake and is known for tourism due to its location on the water. Opposite, and on the other side of the land mass, is the Green Bay area which is a large bay of Lake Michigan between Door County and the city of Green Bay. These sales are all aligned along the lake shore which has high bluffs with dynamic lake views. Any residence found in either area would be oriented toward the lake vista and not inwards toward the wind turbines. In addition, Algoma is over 5 miles to the east of the nearest wind turbines, which are not visible. The same is true of the other urban areas and the Green Bay shoreline. This opinion is supported on the chart found on page 101 which lists only 5 sales with either a substantial or extreme view of the wind turbines. Lastly, it was this same area that homes were purchased by the wind farm developer who then either razed the buildings or resold the property at a substantial loss. This information appears not to be included in the study.

Few Sales in Close Proximity to Wind Turbines

The study utilized approximately 7,500 residential, improved sales. Of this number, only 67 sales (<1%) were within 0.57 miles of a wind turbine and 63 sales (<1%) had a substantial or extreme view of the wind turbines. Conversely, 98% of all the sales were a mile or greater in distance away, with the greatest number being over 3 miles away (57%).²²⁷ The author correctly states that view or vista is a significant factor in value. The study has a chart showing that a poor vista results in a -21% loss of value and a below average vista results in a -8% loss.²²⁸ However, when this vista measurement was applied to substantial and extreme views of the wind turbines it found the opposite to be true, indicating a +2.1% increase in value by having an extreme view. This result is counter-intuitive: Common sense and experts in the real

227 Berkeley study, xiii, xiv.

228 Ibid, 29, Figure 5.

estate field would agree that a wind turbine meets the definition of a poor vista. Surely, a wind turbine does not enhance the vista. When the study compared proximity to the wind turbines (which may overlap the Vista factor) it found a -5.3% to -5.5% loss in value.²²⁹ It would appear that the problem lies in the number of samples in close proximity with a clear view of the wind turbines as suggested by the author regarding the proximity factor not being significant in statistical terms: "Even though the differences are not found to be statistically significant, they might point to effects that exist but are too small for the model to deem statistically significant due to the relatively small number of homes in the sample within 1 mile of the nearest turbine."²³⁰ Though a -5.5% loss in value may not be substantial in the field of statistics, it is substantial in the valuation of real estate as any appraiser or property owner would know. This type of loss would equate to a \$13,750 loss for a \$250,000 home.

Other Studies Have Found a Negative Impact

Though the Berkeley study found no loss of value for an improved residential property due to proximity to a wind farm, other studies have suggested otherwise. The study's author acknowledges this very point, listing the studies he found in his literature research regarding the impact of wind turbines on real estate values. In the chart found on page 9, the author notes that 3 out of 4 (75%) of the homeowner surveys found a loss; 3 out of 5 (60%) of the expert surveys found a loss; 2 out of 10 (20%) of the transaction analysis-simple statistics found losses; and 3 out of 4 (75%) of the transaction analysis-hedonic model found losses. As a matter of fact, the only two studies authored by certified real estate appraisers (McCann, Kielisch) both found significant losses and the only hedonic model study listed in this chart that did not find a loss was the Berkeley (Hoen) study.

It would appear that the Berkeley study is only one of a few that have resulted in finding no impact on property value due to the presence of wind turbines. One reason for this could go back to the very base of the model, the selection of improved residential properties and their limitation to extract values due to the complexity and sheer number of the variables to value that interplay with the final market value. Another reason is cited by Heintzelman stating, "However, they limit themselves to discontinuous measures of proximity based on having turbines within 1 mile, between 1 and 5 miles, or outside of 5 miles, or a similar set of measures of the impact on scenic view, and they again find no adverse impacts from wind turbines. In addition, by including so many disparate regions within one sample they may be missing effects that would be significant in one region or another."²³¹

Another potential reason for their finding of no impact could be the lack of adequate numbers of sales within close proximity to the wind turbines for their statistical study to work properly. The author identified this as problematic, saying, "Unfortunately for the study, most wind power projects are not located near densely populated areas. As a result, finding a single wind project site with enough transaction data to rigorously analyze was not possible."²³² This, of course, is a prejudice of many academic statisticians, but it is not shared with the appraisal profession as indicated by this statement from a guide to statistical analysis by the Appraisal Institute, "Based on the experience of the authors, the

229 Ibid, 31.

230 Ibid, 31.

231 Martin D. Heintzelman, Ph.D. & Carrie M. Tuttle, *Values in the Wind: A Hedonic Analysis of Wind Power Facilities* (Clarkson University, 2011), 8-9.

232 Berkeley Study, 10.

ideal number of sale properties usually ranges between 18 and 32.”²³³ Indeed, a smaller, localized study may be a much better analysis to isolate the impact on property value of a wind turbine than a combination of 10 different studies in nine states.

Conclusion

This brief review touched on several major points to consider when looking at the Berkeley study. It showed that the base of the study (that is, to use improved residential sales) has a great potential to result in flawed conclusions due to the great number of value variables present in such properties. A vacant land analysis would have been better and more accurate. The selection of sales combining both urban (city) and rural sales is flawed on the onset since these two buyer groups are very different from each other and have different motivations for their purchases. Of course, the reason the two were combined was due to the lack of a large number of sales in and around the wind turbines themselves. This could suggest to the authors that: (a) possibly this lack of sales activity is due to the presence of the wind turbines themselves; or (b) the sales sample set and model should be smaller, potentially resulting in a more accurate measure of the effects. The desire for a large database caused the authors to combine ten different studies located in nine different states, states that were decidedly different from each other, which resulted in a larger database pool. However, on the practical side of real estate valuation, such a large database is not representative of greater accuracy. It could be that these basic errors in judgment were a result of the lack of professional and practical experience in the real estate valuation field.

This is a study of improved residential properties, which overwhelmingly were located in urban centers, not the rural countryside. This study did not measure impacts to agricultural land, recreational, or rural residential land. Therefore, its direct application to such properties is cautioned.

233 *A Guide to Appraisal Valuation Modeling* (Chicago: Appraisal Institute), 61.

Impact of Industrial Wind Turbines on Residential Property Assessment in Ontario, 2012 Assessment Base Year Summary

The Municipal Property Assessment Corporation (MPAC) completed this study to review their assessment practices with regard to the potential negative impact to property value caused by the presence of wind turbines. MPAC is a governmental agency responsible for the assessment of millions of properties in the Ontario, Canada, region. This agency is both political and governmental. Political since the directors are politically appointed and governmental in that a finding of a negative value impact due to the wind turbines would require the local assessors to revalue such impacted properties and the governmental agencies that are dependent upon tax revenue from property assessments would be negatively impacted. With this responsibility, the MPAC went about testing the null hypothesis that there is “no difference between properties in close proximity to wind turbines to those that are not.” (A null hypothesis in statistics basically assumes no difference between two sets.) MPAC chose to test this hypothesis through the use of checking the accuracy of their assessments by comparing the two sets and then using statistical analysis of selling prices to test if there is a valuation impact.

The first test examined the accuracy of the assessments in the two data sets, one being less than 2km proximity to a wind turbine and the other outside of that distance (>2km). Using Canadian government assessment standards of accuracy, which state that an assessment is considered accurate if the assessment-to-sale price (ASR) lies within 0.95 to 1.05 of the assessment. An ASR ratio is calculated by assessment ÷ sale price. As an example, if a property was assessed at \$100,000 and sold for \$105,000 the ASR would be 0.952 or 95% of the assessed value and the assessment would be considered accurate. If the property sold for \$90,000 the ASR would be 1.11 or 111% of the assessed value and the assessment would fail the accuracy test.

The geographic area of this study was fifteen market areas in Ontario, Canada. These areas were identified as potential study markets since wind turbine farms were in their vicinity. MPAC tested the assessment ratios pre-construction of the wind farms (but after their announcement) and after the construction of the wind farms. The hypothesis was if the ratios were within the acceptable range, i.e. 0.95 to 1.05, for both data sets and in both conditions, then there was no relationship between the presence of wind turbines and value.

The test of the ASR showed those properties within the 2km distance of wind turbines had a -4.2% to -4.5% loss factor. Since this was within the $5\% \pm$ acceptable range of value, MPAC concluded wind turbines do not impact property value. It should be noted that the overall property values that were <2km were consistently less than those values >2km (MPAC report, figure 2, p.18) and their ASRs were higher, typically over 1.034 as compared with the >2km properties which were in the 0.992 range.

The second test was a sales analysis using multiple regression analysis. This study indicated that only two market areas had sufficient pre-construction and post-construction sales to derive a variable for this comparison. One of these areas, market area 26RR010-Chatham, indicated a loss of \$6,451 per property if <1km of a wind turbine and a loss of \$3,686 if within the 1km-2km distance. Both statistics were considered not statistically significant since they were at the 10% significance level.

Overall, the study concluded that distance to a wind turbine was not a factor influencing property value.

Critique

The first test of the study had little to do with measuring the impact on property value due to the presence of a wind turbine and everything to do with measuring the accuracy of assessments. There is nothing said in the report to investigate if the local assessors had already considered the locational factor in their assessment. So, if a home that was located outside of the zone of influence and would have a value of \$125,000 and assessed accordingly, and a similar home that laid within the zone of influence would have a value of \$100,000 and assessed accordingly, the ASR for both subsets would be 1.00. Accordingly, if you applied the MPAC test of ASRs you could conclude there is no influence due to the wind turbines. Hence, this first test was simply an exercise in measuring their accuracy of assessment and not to extract an impact factor.

The second test had some issues as the charts illustrated. For instance, in only two out of the fifteen market test areas did they have sufficient sales to measure both the pre-construction and after-construction values, which was the stated purpose of this exercise. Additionally, one of the two areas indicated a measurable (though not deemed significant) negative effect. Of course, the problem here, as with the Berkeley study, is that there were few variables measured for the improved properties. Limiting these value-influencing variables is a mistake that will skewer the results of any study. The study itself did not provide any insight into the other variables to be considered and why or why they were not included. It can be said with consistency that this study indicated properties within close proximity of the wind turbines had overstated assessments and lower valued properties.

Case Study Diminution in Value Wind Turbine Analysis (2012)

Real estate appraiser Ben Lansink, AACI, P.Appr, MRCS, real estate appraiser (Ontario, Canada) completed a comparative sales analysis study of five properties located within a wind farm area. These properties were selected because they were purchased by the Canadian Hydro Developers, Inc (Hydro) who was the developer of the Melancthon Wind Facility (MWF) located in Shelburne, Ontario, Canada. MWF is a 200-megawatt development comprised of one hundred and thirty-three General Electric 1.5mw wind turbines having 262ft± tall towers and a 147ft± blade wingspan. The wind farm was developed in two phases, with the first phase coming online in 2005 and the second in 2008. Hydro purchased these five properties at the property owners' request and paid full market value for each property according to Lansink. The purchases were completed between 2005-2007, and the resale of the properties took place between 2009-2012. Lansink inspected all the properties in 2012, compared the results of the personal inspection with the MLS listings at the time of purchase and resale to note any changes that may have taken place. The five properties consisted of four single-family residences and one farm.

Lansink used a comparative analysis of twenty comparable properties sold in 2005-2007 to measure the validity of the initial purchase price concluding that the properties were purchased at market value without consideration given to the value influence of the wind farm. He then proceeded to do a market trend study in the area to establish a measurable and reasonable adjustment for time. He then applied this market trend adjustment to predict the market value of the properties sold at a later date and compared that estimate to the actual sale price. The difference, if any, was applied to the wind farm influence having all other factors being equal. He concluded the following:

Sale 1- This property was a 1.5-story Cape Cod design residence on 1.88 acres. Its room count was 6 total rooms, 3 bedrooms and 2 bathrooms (6/3/2). The closest wind turbine was 1,902ft away. The home was purchased in November 2007 for \$500,000 and sold two years later in December 2009 for \$288,400. The condition of the home was considered the same in both sale dates. When the market trend adjustment was factored the estimated resale price was \$557,509 representing a -48.27% loss due to the wind turbine. If no market trend adjustment was applied, the loss would be -42.32%.

Sale 2- This property was a 2-story farmhouse residence on 100± acres. Its room count was (13/4/2) with 3,500sf of gross living area. It had a large Quonset agricultural building. The closest wind turbine was 1,902ft away. The home was purchased in October 2007 for \$350,000 and sold about three years later in November 2010 for \$175,000. The condition of the home was considered the same in both sale dates. When the market trend adjustment was factored, the estimated resale price was \$422,272 representing a -58.56% loss due to the wind turbine. If no market trend adjustment was applied the loss would be -50.00%.

It should be noted that Hydro chose to market the property as "vacant land," however Lansink inspected the property and found the buildings viable and considered the sale "as improved."

Sale 3- This property was a 2-story contemporary design residence on 10± acres. Its room count was (6/3/1) and included a 2-car garage and raised wood decks. The closest wind turbine was 664ft away. The home was purchased in January 2007 for \$305,000 and sold two and

a half years later in August 2009 for \$278,000. The condition of the home was considered the same in both sale dates. When the market trend adjustment was factored, the estimated resale price was \$362,153 representing a -23.24% loss due to the wind turbine. If no market trend adjustment was applied the loss would be -8.85%.

Sale 4- This property was a split-level design residence on $1\frac{1}{2}$ acre. Its room count was 10/5/2 and had a 1-car attached garage. The closest wind turbine was 1,136ft away. The home was purchased in August 2007 for \$302,670 and sold two years and nine months later in April 2010 for \$215,000. The condition of the home was considered the same in both sale dates. When the market trend adjustment was factored the estimated resale price was \$293,172 representing a -26.66% loss due to the wind turbine. If no market trend adjustment was applied the loss would be -28.97%.

Sale 5- This property was a bi-level design residence on $2\frac{1}{2}$ acre and had a 2-car attached garage. The closest wind turbine was 1,213ft away. The home was purchased in June 2005 for \$299,000 and sold seven years later in June 2012 for \$250,000. The condition of the home was considered the same in both sale dates. When the market trend adjustment was factored the estimated resale price was \$398,723 representing a -37.3% loss due to the wind turbine. If no market trend adjustment was applied the loss would be -16.39%.

Depending on how you calculated the losses, either from the estimated market value at the date of resale or the difference between the purchase and resale price with no consideration for the time lapse, the analysis found the following losses:

Market trend method:

Median loss	-37.30%
Average loss	-38.81%

The difference between purchase and resale method:

Average loss	-29.31%
--------------	---------

If you isolate the impact on only rural residences having less than 10 acres (excluding Sale 2), then the losses change slightly.

Market trend method:

Average loss	-33.87%
--------------	---------

The difference between purchase and resale:

Average loss	-24.13%
--------------	---------

In summary, the study indicated that the presence of a wind turbine in close proximity (664ft to 2,531ft) resulted in significant value losses ranging from an average of -24% to -39%.

Glen Taylor Chevron Wind Tower Market Study - Wyoming

In 2010, realtor Glen Taylor (Equity Brokers, Casper, Wyoming) completed an informal market study of the residential properties in close proximity to the Chevron Wind Tower Development. The area of study was in Evansville, Wyoming just outside of Casper. The wind farm had 11 wind turbines. Mr. Taylor based his study on observations of market activity both in near proximity to the wind farm and out of the wind farm influence. His study concluded:

“My determination was that the presence of the large Wind Towers has had a detrimental effect on property values, not only residential property values, but also unimproved and presently uninhabited properties as well. Keep in mind; these now uninhabited properties may someday be candidates for development of residential or small ranchette type of locations. The report also indicates that those properties closest to the development are the most affected by the huge towers close to adjacent property lines and my 20 years of experience in the real estate marketing business tells me that the further away the towers are from adjacent property lines, the less affected the property values would be. The term “further” may be the key word here as it can be a very subjective term.”²³⁴

²³⁴ Letter to Converse County Commissioners, November 2, 2010, from Glen Taylor.

Appraisal Group One Study - Wisconsin

In the fall of 2009, Appraisal Group One (now, Forensic Appraisal Group, Ltd, Wisconsin) completed a study entitled "Wind Turbine Impact Study – 2009" for the Calumet County Citizens for Responsible Energy, a group of property owners united to prevent wind farms from being located in their county. The study examined the impact that wind turbines have on rural residential property value. The wind turbines that were the focus of this study are approximately 389ft tall and produce 1.0+ megawatts each. This study was based in Dodge and Fond du Lac Counties, Wisconsin. It was broken down into three parts: A literature study, a realtor opinion survey, and sales studies.

Overall, the study concluded that the presence of a wind farm had a negative impact on rural residential property value 5 to 10 acres in size, and farmettes up to 20 acres in size. The impacts according to the realtor survey suggested losses ranging from 24% to 43%; the literature study indicated losses averaging 20.7%, and the sales study indicated losses ranging from 19% to 74% – with the most likely range of loss being 19% to 40%. Some observations of this study and its conclusions follow.

Realtor Survey

The purpose of the realtor survey was to learn from the people who are on the first tier of the buying and selling of real estate what they thought of wind turbines and their impact on residential property value. This survey was designed to measure what type of impact (positive, negative, or no impact) that wind turbines have on vacant residential land and improved property. The questions were designed to measure three different visual field proximity situations to wind turbines. These three were *bordering* proximity (defined as 600ft from the turbine), *close* proximity (defined as 1,000ft from the turbine) and *near* proximity (defined as one-half mile from the wind turbines). In all situations, the wind turbines were visible from the property.

Graphics and photographs were utilized to illustrate each question so that the survey taker would have the same or similar understanding as others on each question. In addition to asking the realtors about the type of impact they expected in each situation, the survey then asked them to estimate the percentage of the impact. Though it is understood that realtors are salespeople and not appraisers, it is also true that they often have to estimate asking prices for their clients or act in the capacity of a buying agent for a client. Both situations demand an estimate of value and recognition of those factors that both benefit and detract from value.

The geographic area for the selection of the survey participants was defined by the wind farm projects. These projects were in Fond du Lac and Dodge Counties, Wisconsin.

A total of 36 realtors were surveyed, indicating an average of 13.4 years of experience.

Figure 1: This is a view of the Blue Sky Green Field wind farm.

The survey indicated that, in all but two scenarios, over 60% of the participants thought that the presence of the wind turbines had a negative impact on property value. This was true of both vacant land and improved land. Where the group diverted from that opinion is when they were presented with a 10-20 acre hobby farm being in *close* and *near* proximity. In these cases, 47% (*close* proximity) and 44% (*near* proximity) of the participants thought that the wind turbines caused a negative impact on property value. The answers showed that *bordering* proximity showed the greatest loss of value at -43% for 1-5 acre vacant land and -39% for improved properties. Next in line was the *close* proximity, showing a -36% value loss for 1-5 acre vacant land and -33% for improved property. Last in line was the *near* proximity, showing a -29% loss of value for a 1-5 acre vacant parcel and -24% loss in value for improved parcels. These losses show a close relationship between vacant land and improved land. This pattern was replicated regarding the *bordering* proximity for a hobby farm, whereas 70% believed it would be negatively impacted. Lastly, the opinions regarding the impact of the wind turbines due to placement (that being in front of the residence or behind the residence) showed that in both situations most participants believed there would be a negative impact (74% said negative to the front placement and 71% said negative to the rear placement).

In conclusion, it was observed that: (a) In all cases with a 1-5 acre residential property, whether vacant or improved, there will be a negative impact on property value; (b) with 1-5 acre properties, the negative impact on property value in *bordering* proximity ranged from -39% to -43%; (c) with 1-5 acre properties, the negative impact on property value in *close* proximity ranged from -33% to -36%; (d) with 1-5 acre properties, the negative impact on property value in *near* proximity ranged from -24% to -29%; (e) in all cases the estimated loss of value between the vacant land and improved property was close. However, the vacant land estimates were always higher by a few percentage points; (f) it appears that hobby farm use on larger parcels would have lesser sensitivity to the proximity of wind turbines than single-family land use; and (g) placement either in front or at the rear of a residence has similar negative impacts.

Literature Study

This study looked at the recent articles and studies published related to the impact of wind turbines on residential property values. The review broke down the articles into several categories including health issues, health solutions, wind turbine hazards, conservation concerns, property values and land use, noise, quality of life, wind energy production, wind farms as tax havens, and economic impact.

Below is a brief summary of the findings:

- Articles and studies show wind turbines:
 - Intrude on the viewshed
 - Make noise
 - Cause flicker and strobe light irritants
 - Limit development
 - Affect highest & best use
 - Increase time on the market
 - Lower property values

- Wind industry cites a 2004 study by the Renewable Energy Policy Project to support their position that there is no impact on property value. REPP is an organization dedicated to advancing renewable energy.
- European countries report property losses from 10% to 30%.
- Realtors overwhelmingly consider wind turbines to have a negative impact on property value.
- Independent appraisers usually find a diminution of land value due to the presence of wind turbines.
- Regarding rural properties, articles indicated that land values are affected by the turbines due to:
 - Incursion into peaceful countryside,
 - Turns farms and land into industrial zones,
 - Flicker, noise and nighttime strobes.
- Adjacent properties are impacted the same as the host landowner but receive none of the compensation.
- Sometimes land values remain the same or increase for the host landowners.
- Value impact decreases with distance from the turbine.

After reviewing the articles and studies on wind energy, the study concluded that wind turbines appear to have a negative impact on the property values, health, and quality of life of residents in close proximity. Of the studies that found no impact on property value, nearly all were funded by wind farm developers or renewable energy advocacy groups. Of the studies and reports showing property loss, the average negative effect is -20.7%.

Additionally, the research shows it is equally reasonable to conclude that some residents in close proximity to wind turbines experience genuine negative health effects from Low-Frequency Noise, infrasound and blade flicker. Of the studies and reports cited, an average setback of little over a mile should significantly lessen detrimental health effects. In addition to noise and flicker issues, disrupted TV and cell phone receptions contribute to a negative impact on the quality of life for residents living in close proximity to wind turbines.

Sales Study

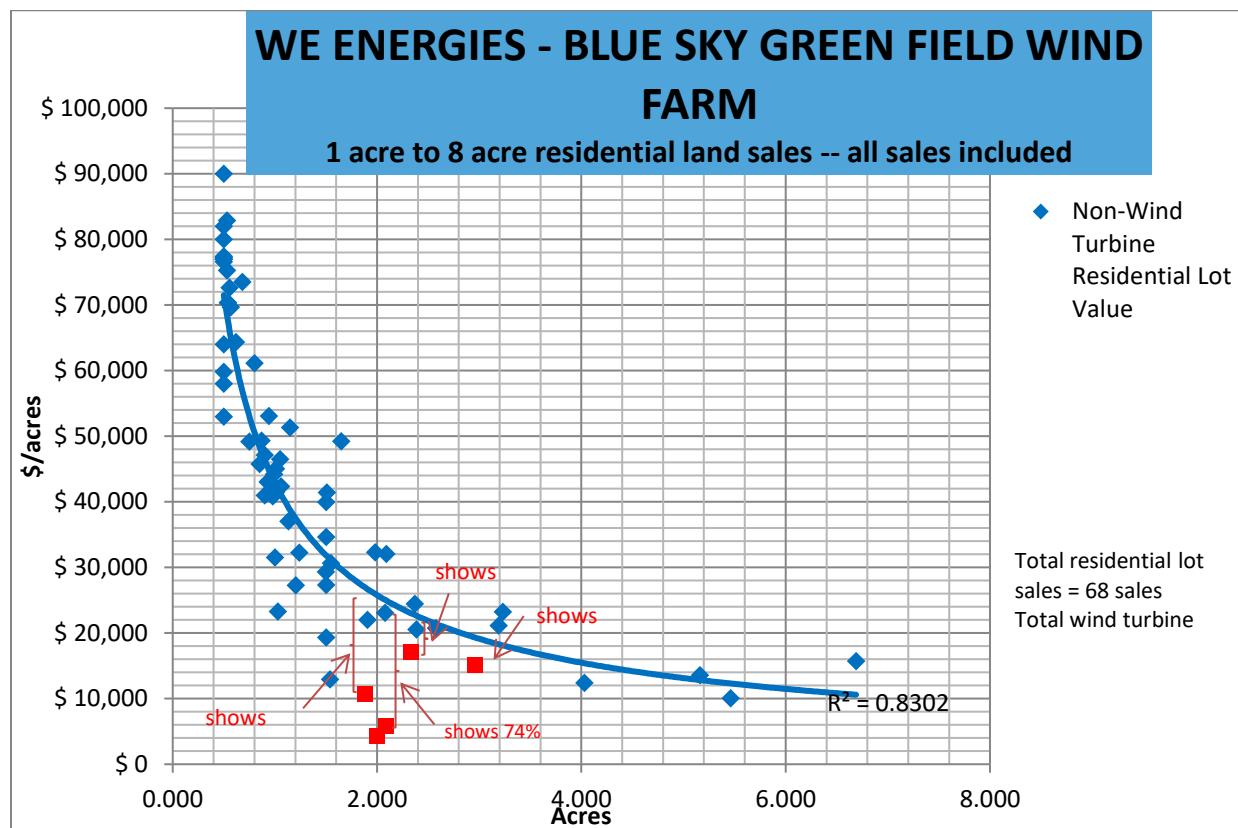

The purpose of the wind turbine impact sales studies was to compare the residential land sales of properties located within the wind turbine farm area to comparable land sales located outside of the influence area of the wind turbines. Being located outside of the influence area meant that the wind turbines could not be seen from the property.

The areas of study include the WE Energies – Blue Sky Green Field wind farm located in the northeast section of Fond du Lac County and the Invenergy – Forward wind farm located in southwest Fond du Lac County and northeast Dodge County, all in the State of Wisconsin. The sales studies and their conclusions follow.

WE Energies – Blue Sky Green Field Wind Farm Sales Study

The area of study was the northeast section of Fond du Lac County bordered by Calumet County to the north, Lake Winnebago to the west and Sheboygan County to the east. The study included the townships of Calumet, Taycheedah, and Marshfield. A total of 68 vacant residential land sales were utilized for this study. From that total, 6 land sales were within the influence of the wind turbines (within the wind farm parameters), and 62 sales were located outside of that sphere of influence. The simple regression analysis graph is found below.

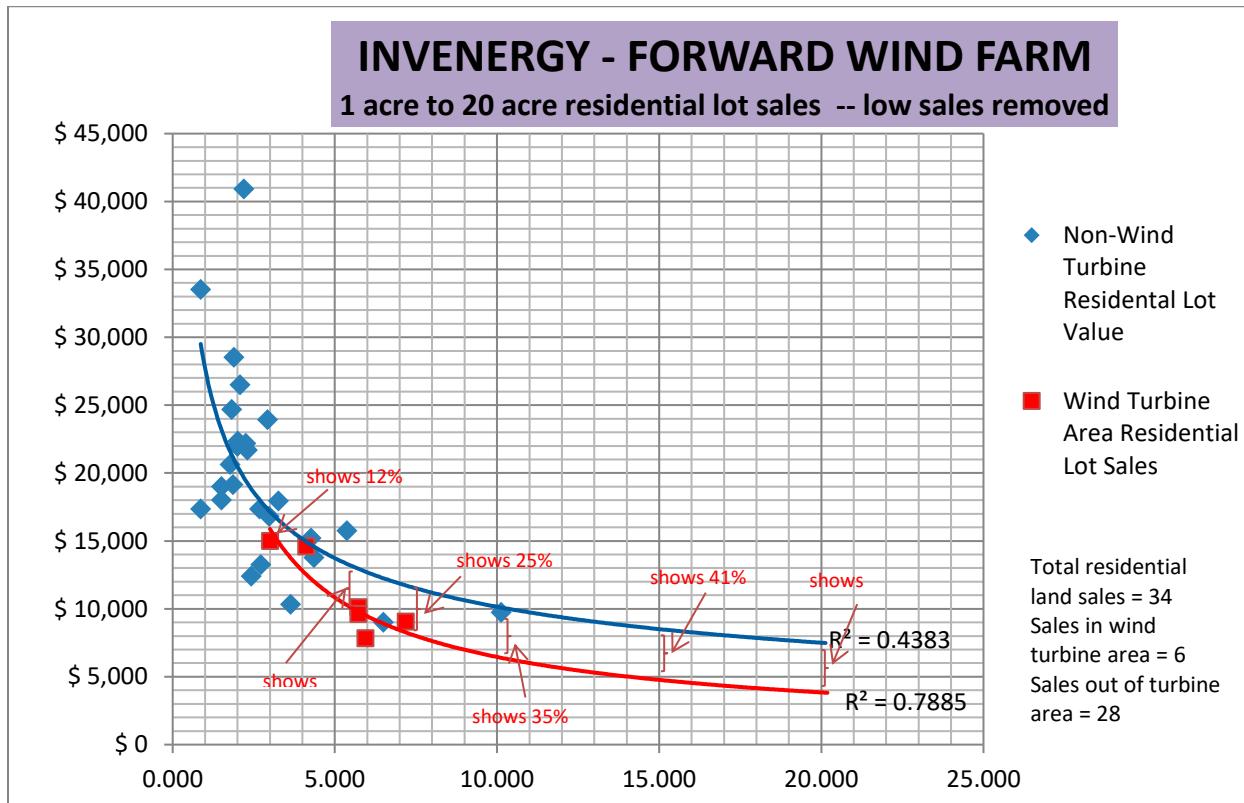

The sales study indicated three factors: (1) Sales within the wind turbine influence area sold for less than those outside of this area; (2) there were substantially fewer sales available within the turbine influence area as compared to those sales outside of the influence area; and (3) the impact of the wind turbines decreased the land values from -19% to -74%, with an average of -40%. Additionally, it can be said with a high rate of confidence that the impact of wind turbines on residential land sales is negative and creates a loss greater than -19%, averaging -40%. It is logical to conclude that the factors that created the negative influence on vacant land are the same factors that will impact the improved property values. Therefore, it is not a leap of logic to conclude that the impact of wind turbines on improved property value would also be negative, most likely following the same pattern as the vacant land sales, that being greater than -19%, averaging -40%.

Invenergy – Forward Wind Farm Sales Study

The area of study was the southwest section of Fond du Lac County and the northeast section of Dodge County being bordered by US Highway 41 to the east and Horicon Marsh to the west. The study included the townships of Oakfield and Byron in Fond du Lac County and Leroy and Lomira in Dodge County. A total

of 34 vacant residential land sales was utilized for this study. From that total, 6 land sales were in the influence of the wind turbines (within the wind farm parameters) and 28 sales were located outside of that sphere of influence. The simple regression analysis graph is found below.

The sales study indicated three factors: (1) Sales within the wind turbine influence area sold for less than those outside of this area; (2) there were substantially fewer sales available within the turbine influence area as compared to those sales outside of the influence area; and (3) the impact of the wind turbines decreased the land values from -12% to -47%, with the average being -30%. Additionally, it can be said with a high rate of confidence that the impact of wind turbines on residential land sales is negative and creates a loss greater than -12%, averaging -30%. It is logical to conclude that the factors that created the negative influence on vacant land are the same factors that will impact the improved property values. Therefore, it is not a leap of logic to conclude that the impact of wind turbines on improved property value would also be negative, most likely following the same pattern as the vacant land sales, that being greater than -12%, averaging -30%.

Conclusion

The sales study indicated that there was a loss in value of rural residential properties from a low of -12% to a high of -74%. The most typical range of loss could be concluded to be in the range of -19% to -40%. This study was for rural residential large acreage properties ranging from 1 to 10 acres. The properties impacted by the wind turbines all had a view of the turbines and were less than one-half mile from any wind turbine. This study did not measure impacts to agricultural land or recreational; therefore, its direct application to such properties is cautioned.

Clarkson University Study (Heintzelman & Tuttle)

On March 3rd, 2011, Assistant Professor Martin D. Heintzelman, Ph.D., and Carrie M. Tuttle, a Ph.D. candidate in Environmental Science and Engineering, Clarkson University, published their study entitled “Values in the Wind: A Hedonic Analysis of Wind Power Facilities.” This study used 11,369 arm’s length transactions of residential and agricultural properties between 2000 and 2009 in Northern New York State to extract the impact of wind farms on property value. They found that the nearby wind facilities significantly reduced property values. Specifically, they found that “Decreasing the distance to the nearest turbine to 1-mile results in a decline in price of between 7.73% and 14.87% on the average.”²³⁵ At the block-group level, the existence of a wind turbine between 1 and 3 miles away impacted property values between -15.6% and -31%.²³⁶

Study area

The study area included three counties in Northern New York State, Clinton, Franklin and Lewis Counties. This area is located in the northeast corner of New York bordering Vermont to the east, Canada to the north and has within the area, Adirondack Park, and Lake Champlain. The area of the study is primarily rural, lightly populated, with small towns and villages. The area of study includes six wind farms which are not within the borders of the Park but are in close proximity. The per capita income analysis for the area indicates that it is less affluent than the rest of New York State. The typical property value in the study was \$106,864.

Conclusions from the Study

The study indicated several factors. First, the impact of a wind farm on property values was significantly negative. Second, distance is a direct factor in the negative influence, and the further the distance the lesser the impact. Last, when measured with properties outside the influence area of the wind farms, the impact can be as great as -32.06% (being within 0.10 miles of a turbine) to -13.79% (being 3 miles away from a wind turbine) when measured as a block-group with fixed effects factored in. A more conservative conclusion, using the repeat sales method, results in an impact of -24.12% (being within 0.10 mile of a wind turbine) to -10.06% (when 3 miles away).²³⁷ Other results showed at the block-group level that the existence of a wind turbine between 1 and 3 miles away impacted property values between -15.6% and -31%.²³⁸

Coral Springs Development Study (Forensic Appraisal Group, Ltd)

The Coral Springs development is located on Boulder Ridge Road across the road from Fish Creek, in Section 34, T13N, R73W, of Albany County, Wyoming. This development is comprised of 7 lots being 35.1 acres to 35.3 acres in size, having a mix of vegetation from spruce and fir trees to grassland and sagebrush. It is in the foothills, having a view of the grassland valley to the east and north. Currently, there are no residences in this development, however, there are some storage buildings built on Lot A. It is improved with private gravel/dirt roads and underground utilities. The development has protective covenants which require stick-built homes - no modular or mobile homes. It has direct access to Boulder Ridge Road which connects with Cherokee Park Road one mile to the east. It is being marketed by Duane Toro Real Estate, Laramie, Wyoming; Duane Toro and Bob Davis, agents. One parcel was marketed by Dean Smith a private property owner. The original development owners are Grant L. Lindstrom and Shane M. Cox.

Sales and Listing History

Since the development began, there have been three lots sold: two lots before the Hermosa West Project was announced and one lot after.

Lot A sold for \$100,000 on July 13th, 2007 to Stanley P. Hobbs as a custodian for Morganna E. & Alexandra L. Hobbs. Lot B sold for \$100,000 on December 12th, 2007 to Dean P. Smith and Diane Smith-Conroy. The listing price on Lot A was \$100,000 and on Lot B \$135,000. These sales were completed before the Hermosa West project was announced. The remaining lots were listed between \$125,000 to \$150,000.²³⁹

Since the Hermosa West project was announced and is known in the area, the owner of Lot B has placed his lot up for sale, asking \$79,000 and sold for \$75,000, June 13, 2010.²⁴⁰ This sale shows a \$25,000 (25%) deduction from its original sold price in 2007. The remaining unsold lots have all been reduced to \$87,000 since November 15, 2010. This reduction ranges from -30% for the lowest lot listed at \$125,000, and -42% for the ones listed at \$150,000.

It would appear that the Smith sale is an indicator of how the market is responding to the proposed wind farm and the remaining listed parcels will sell for much less than the new asking price. Investigating the reason for the decrease in unsold lot prices, two factors were uncovered that played a part: The sluggish economy and the Hermosa West project. According to the seller, the Smith property was put up for sale

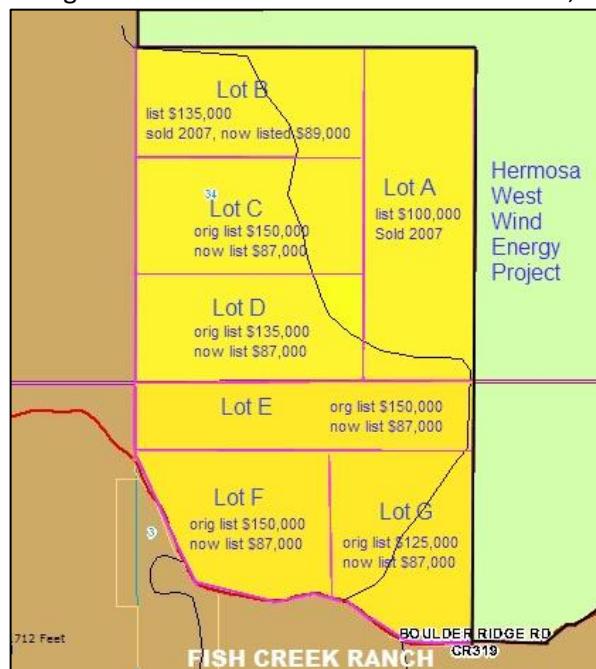

Figure 2: The Coral Springs development is highlighted in yellow with the original and new listing prices noted per lot. The Hermosa West project is highlighted in light green. Fish Creek is located just south of the development.

239 Information confirmed with listing broker, Bob Davis.

240 Information confirmed with Bob Davis, Michelle White, and court records.

due entirely to the Hermosa West project which is proposed to abut the Coral Springs development to the east and north.²⁴¹

Observations and conclusions

It is apparent that, though the sluggish economy in the Wyoming real estate market can be attributed to some of the declines in property value, the Hermosa West project appears to be the dominating factor, indicating a negative impact on value with a potential range of -25% to -44%, showing an average of -35%.

241 Information confirmed with Dean Smith.

McCann Value Impact Study

Michael S. McCann, CRA, a state licensed Certified General Appraiser (Illinois), completed a study of improved residential properties in the Mendota Hills wind farm area (Lee County, Illinois). This study was completed for property owners who were disputing the claims of another wind farm developer that wind farms do not have an impact on residential property value.

Mendota Hills wind farm is located near the village of Paw, Lee County, Illinois, and operated 63 wind turbines at the time of the study. Each wind turbine stands 214ft from ground to the hub and has three 85ft long blades. It was constructed in June-November 2003. It was the first utility-scale wind farm in the state.

Mr. McCann compared the average sale price \$/GLA of fifteen residences located within two miles of the Mendota wind farm to the average sale price \$/GLA of thirty-eight residences located greater than two miles from the Mendota wind farm. The time period of this study was 2003-2005 when the residential market was very robust in the Lee County area.

The study indicated the following values:

STUDY GROUP	LOCATION	VALUES
GROUP 1	Within 2-miles of Mendota wind farm	\$ 78.84 sf
GROUP 2	Greater than 2-miles of the Mendota wind farm	\$104.72/sf
	Difference in sale price per GLA	\$ 25.89/sf
	Average diminution of value of residences within 2-miles of the wind farm	-25%

Mr. McCann concluded that the presence of the Mendota wind farm had a -25% impact on residential improved properties that were located within two miles of the wind farm.

Big Sky Wind Farm (IL) Matched Pair Analysis (Paired Data Analysis)

A matched pair analysis study using residential sales outside of the Big Sky Windfarm was completed in July 2015, by Kurt C. Kielisch (Forensic Appraisal Group, Ltd, Wisconsin). A matched pair analysis (a.k.a. paired data sales analysis) is defined as “a procedure used in the direct sales comparison approach to estimate values of specific property characteristics in order to find a value of the subject property. Property sales are paired with similar property characteristics.”²⁴² The Appraisal Institute’s text further defines paired data analysis as: “A quantitative technique used to identify and measure adjustments to the sales prices . . . of comparable properties . . . to isolate the single characteristic’s effect on value . . .”²⁴³ The isolated variable, in this case, was the impact that wind farms, i.e. wind turbines, have on residential property value.

This wind farm is located in Lee and Bureau Counties centered around Ohio, Illinois. Big Sky is a 22,400-acre project area generating 240MW through one-hundred and fourteen 80-meter tall wind turbines of 2.1MW each.

242 The Language of Real Estate (1991). Jeffrey D. Fisher, Robert S. Martin and Paige Mosbaugh. Real Estate Education Company, Chicago. Pg 137.

243 The Appraisal of Real Estate 14th Edition (2013), Appraisal Institute, Chicago, Pg 399.

The scope of work (SoW) followed for this analysis was:

1. Collect all topographical and aerial maps of Big Sky which show the placement of the wind turbines.
2. From the Big Sky wind turbine placement map, create a study map indicating three zones: zero zone which is within the confines of the wind farm, 1-mile zone which is a band approximately one mile wide generating from the perimeter of the zero zone and 3-mile zone which is a band approximately 3-miles wide generating from the edge of the zero zone.
3. Search for all residential sales found within the three zones from January 1st, 2011 to present to make certain all sales took place right before or after Big Sky was in operation.
4. Utilize MRED (MLS), Zillow, and assessment records as our research tools for finding sales.
5. Once sales were discovered confirm the sale was not a foreclosure, short sale or non-arms-length transaction. Remove all non-sales from the study.
6. Using the remaining sales search for comparable sales within the non-impact zone (greater than 5-miles from the edge of the zero zone, or sales less than this distance that cannot see the wind turbines). Keep the parameters narrow as to the dates of sale, gross living area (GLA), size of parcel, style of residence, number of outbuildings, and location.
7. Confirm that the comparable sales discovered are all arms-length transactions. Remove the sales that did not fit this category.
8. Pair up the “wind farm zone” sales with comparable non-wind farm sales. Remove all wind farm zone sales that did not have adequate comparable sales.
9. Locate all sales on a study map.
10. View all sales confirming the data description from our sources, take pictures and note location and view of wind turbines. Remove wind farm zone sales that do not have a view of wind turbines.
11. Confirm all wind farm zone and comparable sales with either the buyer, seller or broker of the transaction, check assessor’s records and get a copy of the transaction deed.
12. Create sales sheets for all sales.
13. Create a sales map of all sales.
14. Complete matched pair analysis of selected wind farm zone sales and their corresponding comparable sale.
15. Utilize Marshall & Swift Cost services, extracted values from sales and other acceptable methods to support adjustments for known variables in the analysis.

The following pages include five matched pair analyses, sales map locating the sales utilized and data sheets of each sale.

No Sales within the Zero Zone

It was interesting to note that there were no residential sales (outside of the Village of Ohio) from January 1, 2011, to July 1, 2015, that was located in the Zero Zone (that zone within the perimeter of the wind farm). Traveling through this area indicated that there were plenty of residential homes, some on larger farm plots and some on smaller residential lots less than 10 acres. It appeared the density of these residential properties were similar to the outside zones (1-mile Zone, 3-mile Zone) yet there were no sales. There appears to be no explanation for this lack of sales activity in an area of 22,400 acres. The lack of sales is interesting and possibly instructive to the impact that wind turbines have on property value. It may suggest that when a property is inside the wind farm it is either not marketable or the property is receiving an income due to the wind turbines that the owner does not want to relinquish. It should be noted that since we have no sales nor did not engage in an in-depth study as to the cause of the lack of sales, any statement on our part the reason is a theory.

Summary of Findings

This analysis through five match pairs indicated that the impact of wind turbines on residential property value is negative ranging from -12% to -25% of the whole property value. The average loss indicated was -19%. The distance of the wind turbines ranged from 0.32 miles to 1.72 miles with the average being 0.65 miles. It was also indicated that often when the wind turbines are not clearly seen from the property that they have little impact on the property value. Now, this conclusion may run counter to the noise, vibration and health concerns, but it may also be true that those issues are only discovered after the sale and hence do not play a part of it.

It was also discovered that there were no sales found within the perimeters of the Big Sky Wind Farm using MRED and Zillow sources, which may indicate that such properties have suffered substantial value loss that it is not viable to sell them (possibly hold and rent).

Twin Groves II Wind Farm –Residential Paired Sales Analysis

Introduction

We completed an impact study to isolate the impact that a wind farm has on improved residential property value located in within and outside of the Twin Groves II wind farm. We attempted to include vacant residential land, however, we found only one land sale in the wind farm, so we excluded this type from the analysis.

The Farm

The wind farm that was selected was the Twin Groves II wind farm located in McLean County, Illinois. This wind farm was selected due to its size, contemporary wind turbines and an adequate number of sales within the identified wind farm.

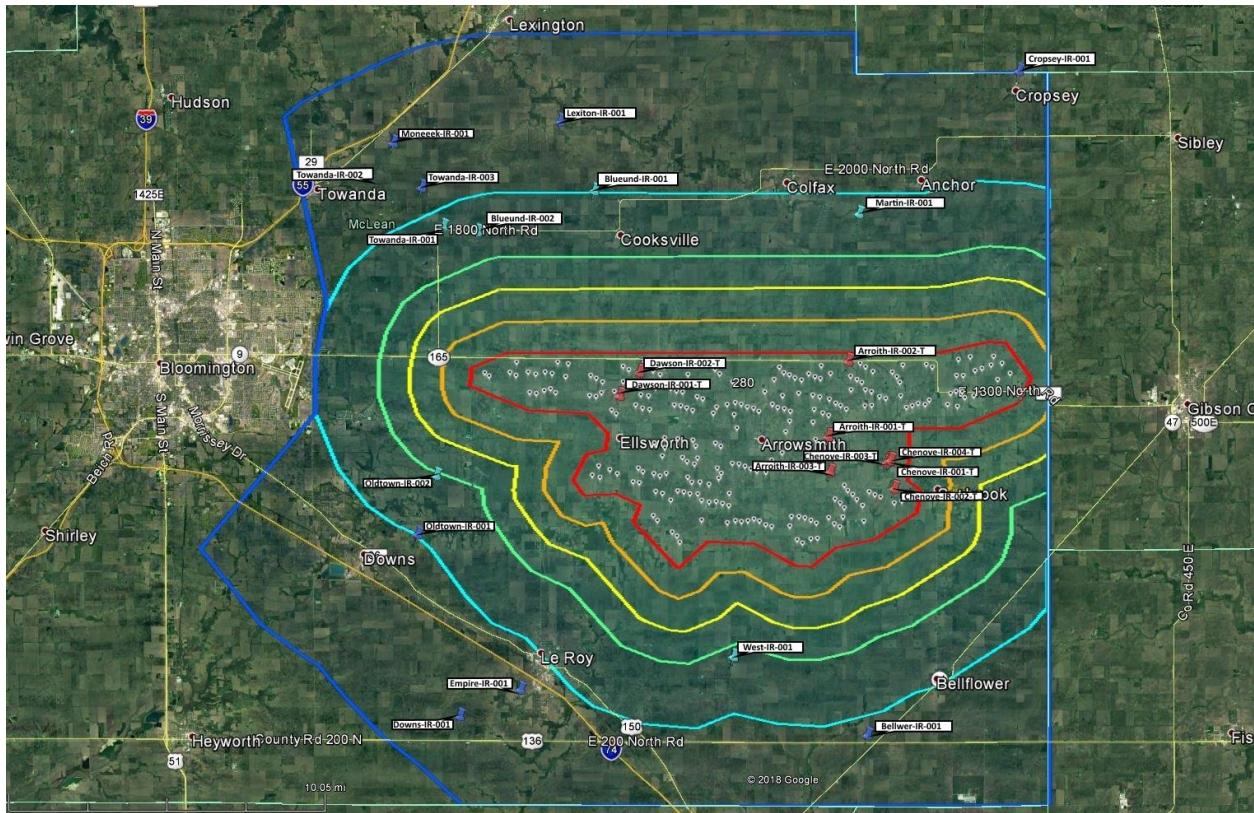

The details of the Twin Grove II wind farm are found in the chart below:

Name	Twin Groves II
Location	McLean County, Illinois, Townships of Arrowsmith, Cheney's Grove and Dawson.
Land area	11,000 acres (approximately half of the two wind farms Twin Groves I & II)
Date of operation	2008
Number of wind turbines	120 wind turbines
Type of wind turbines	Vestas V82 1.65 MW Wind Turbines (<i>picture on next page</i>)
Size in kW of wind turbines	1.65MW each x 120 turbines = 198MW
Hub height of wind turbines	80m (280ft±)
Diameter of Turbine	82.0m (269ft±)
Turbine height	Hub ht + ½ diameter of rotors = 80m + ½ (82m)= 121m (397ft±)
Maximum MW output	Approximately 198MW

Scope of Work

The scope of work to complete this study included:

- Research, collect data and confirm information regarding the Twin Groves II wind farm.
- Locating the wind farm on Google Pro mapping software, locate all the wind turbines within the wind farm and create the wind farm zone and concentric 1-mile zones radiating out from the farm to locate comparable sales as indicated on the map (*see next page for working map*).
- Research and collect sales of improved residential properties within the wind farm, Zone 0.
- Research and collect sales of comparable improved residential sales in Zones 1-5.
- Collect sales data, property data and assessor's data on all sales.

Visit each sale Figure 4: the red line outlines the wind farm Zone-0, orange line is Zone-1, yellow line is Zone-2, green line is Zone 3, light blue line is Zone 4 which has a two-mile width and the dark blue line is Zone 5 which has a five-mile width.

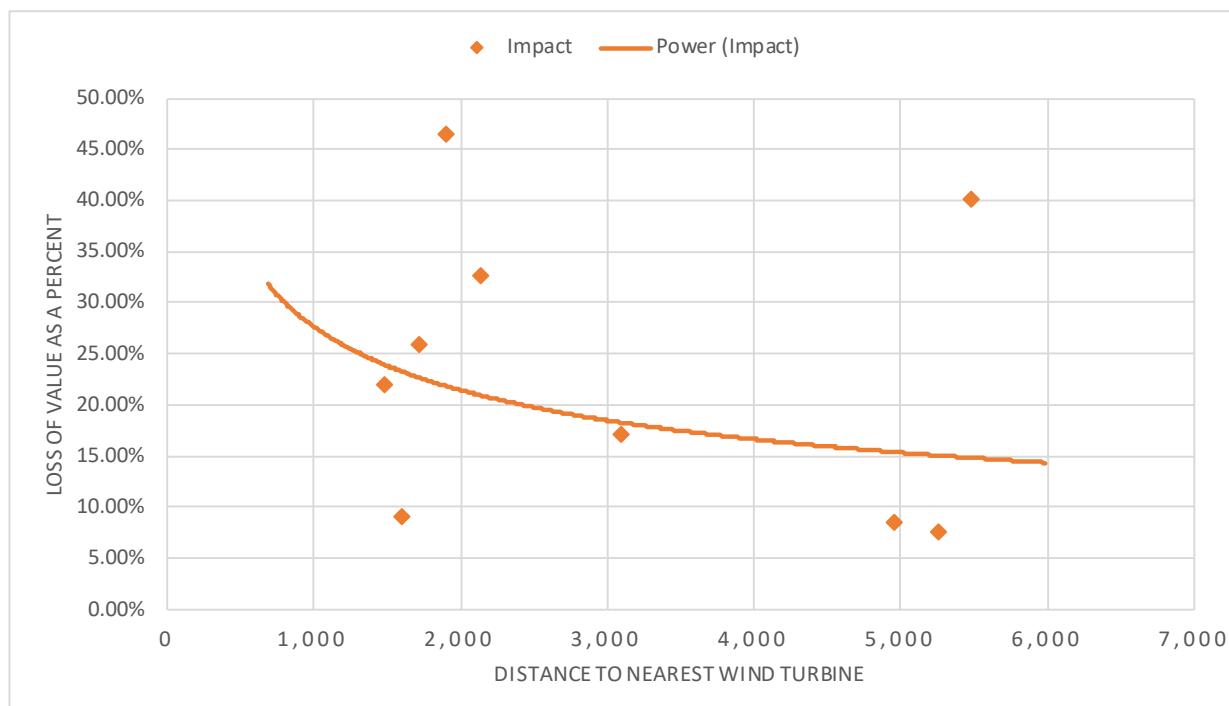

- on-site, take photographs, make field notes and try to confirm sale with the current property owner.
- Send confirmation requests to those sales not confirm in the field.
- Collect sales and support data from the McLean County Court House.
- Complete sales information data sheets.
- Complete a cost approach for each sale using the Marshall & Swift Cost Handbook and Valuation Service.
- Extract Effective Age of each sale using the Cost Approach.
- Complete Paired Sales analysis for each comparable Zone 0 sale.
- Extract the impact of the wind farm from the Paired Sales analysis.
- Using mapping services, locate the nearest wind turbines to each Zone 0 sale, map them and measure the distance from the turbine to the residence.
- Complete a sales map for each Zone 0 Paired Sales analysis.

Conclusions

The conclusions of the nine paired sales are found in the following table:

Pairing	Impact	Type of Residence	Gross Living Area	Age (year built)	Distance to nearest wind turbine
C	-22.0%	Ranch	1,858 sf	1987	1,483 ft
D	-7.7%	One story	2,290 sf	1992	5,259 ft
E	-46.6%	One story	2,089 sf	2008	1,896 ft
F	-25.9%	1.5 story	1,100 sf	1909	1,722 ft
G	-8.5%	Two story	2,271 sf	2001	4,950 ft
H	-40.2%	Tri-level	1,901 sf	1977	5,481 ft
I	-32.8%	Two story	1,728 sf	1880	2,129 ft
J	-17.2%	Two story	2,016 sf	1911	3,094 ft
K	-9.2%	Two story	2,054 sf	1920	1,591 ft

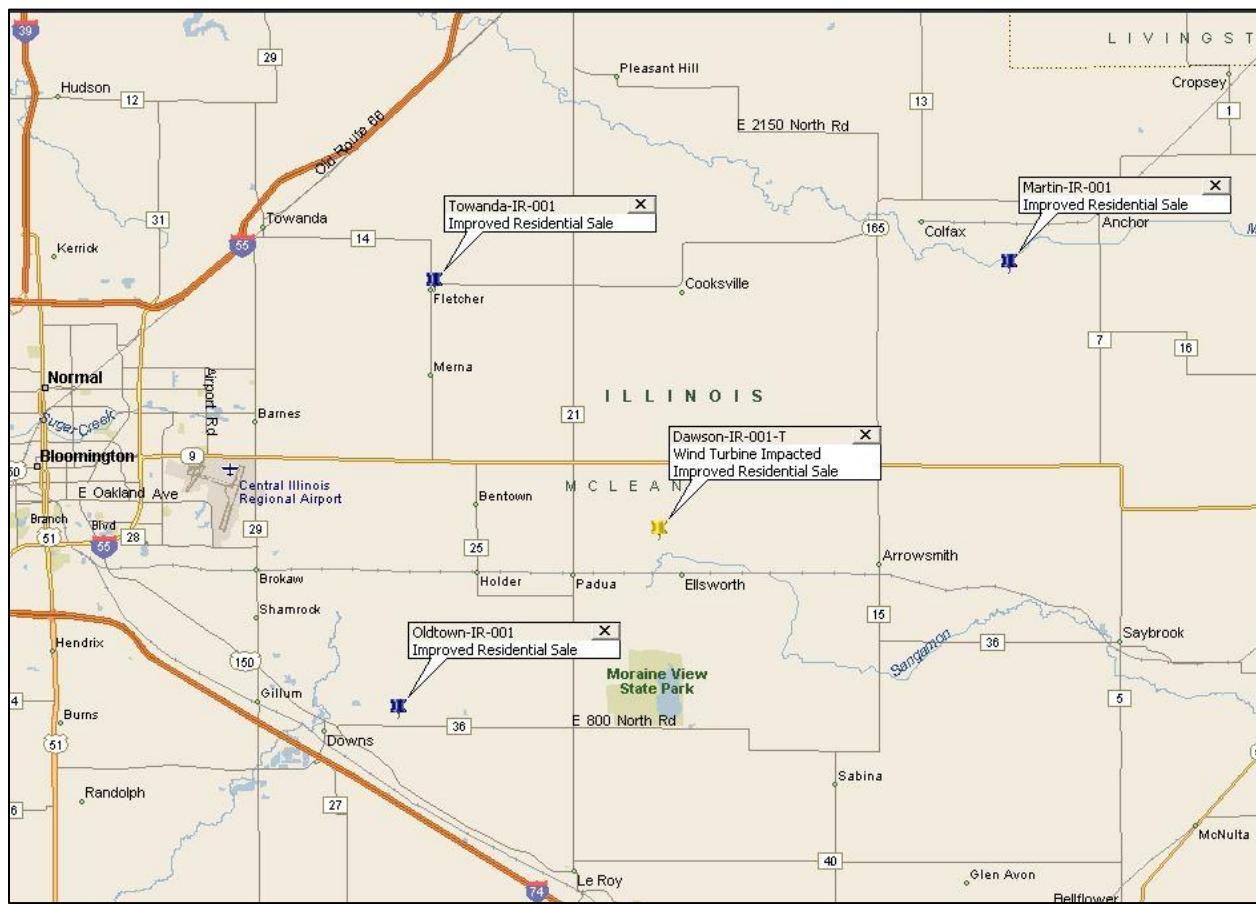

This table was put into the following graph to test if distance had a factor in the impact:

This chart clearly indicates that there is a relationship between distance from a wind turbine and impact to value that a wind turbine causes. It can be said with confidence, that the closer a wind turbine is to a residence the greater negative impact it has on value.

The location map, the analysis, corresponding cost approach and sales sheets for each Paired Analysis follows.

Twin Groves II Wind Farm – Regression Analysis of Agricultural Vacant Land

Introduction

We completed a regression analysis study to isolate the impact that a wind farm has vacant agricultural property value located within and outside of the Twin Groves II wind farm. Since we had a high level of homogeneity of sales and an adequate number of sales, we were able to utilize the valuation methodology of multiple-regression analysis.

The Farm

The wind farm that was selected was the Twin Groves II wind farm located in McLean County, Illinois. This wind farm was selected due to its size, contemporary wind turbines and an adequate number of sales within the identified wind farm.

The details of the Twin Grove II wind farm are found in the chart below:

Name	Twin Groves II
Location	McLean County, Illinois, Townships of Arrowsmith, Cheney's Grove and Dawson.
Land area	11,000 acres (approximately half of the two wind farms Twin Groves I & II)
Date of operation	2008
Number of wind turbines	120 wind turbines
Type of wind turbines	Vestas V82 1.65 MW Wind Turbines (<i>picture on next page</i>)
Size in kW of wind turbines	1.65MW each x 120 turbines = 198MW
Hub height of wind turbines	80m (280ft±)
Diameter of Turbine	82.0m (269ft±)
Turbine height	Hub ht + ½ diameter of rotors = 80m + ½ (82m)= 121m (397ft±)
Maximum MW output	Approximately 198MW

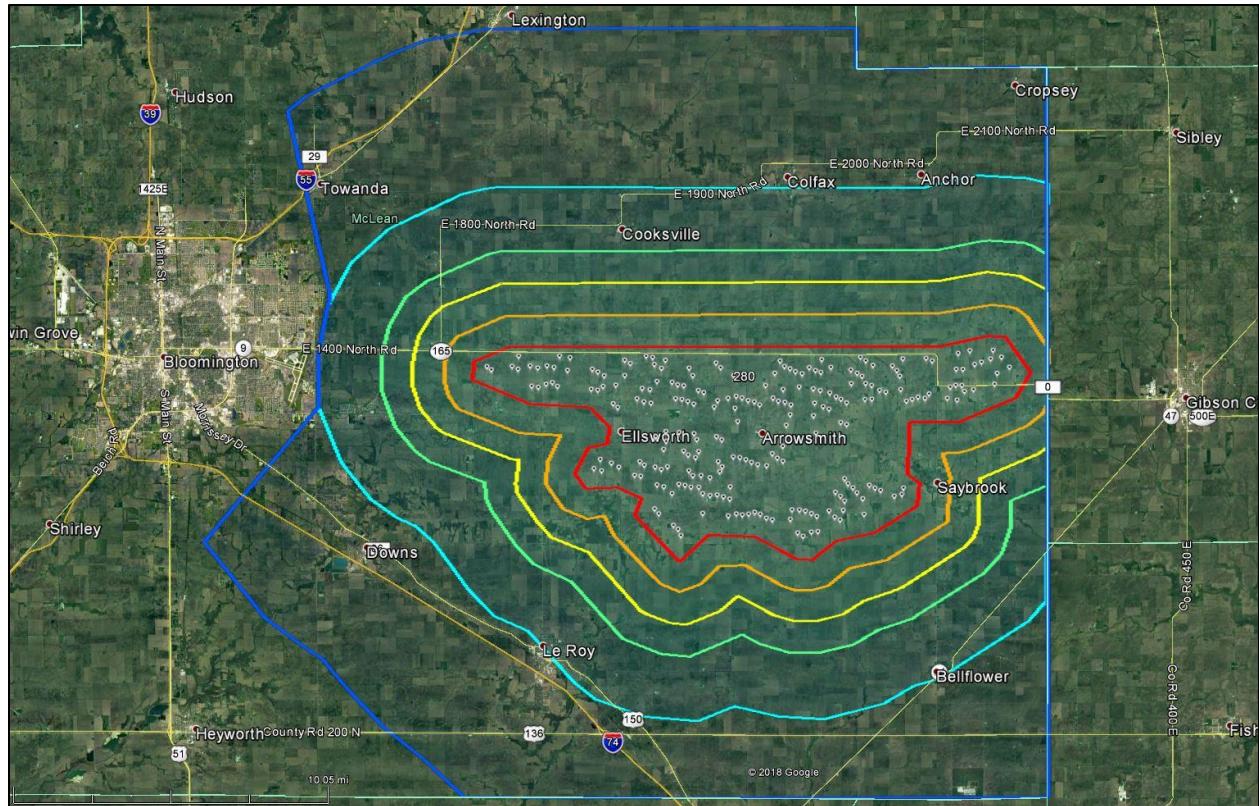

Figure 23: the red line outlines the wind farm Zone-0, orange line is Zone-1, yellow line is Zone-2, green line is Zone 3, light blue line is Zone 4 which has a two-mile width and the dark blue line is Zone 5 which has a five-mile width.

Scope of Work

The scope of work to complete this study included:

- Research, collect data and confirm information regarding the Twin Groves II wind farm.
- Locating the wind farm on Google Pro mapping software, locate all the wind turbines within the wind farm and create the wind farm zone and concentric 1-mile zones radiating out from the farm to locate comparable sales as indicated on the map (*see next page for working map*).
- Research and collect sales of agricultural land sales within the wind farm, Zone 0.
- Research and collect sales of comparable agricultural land sales in Zones 1-5.
- Collect sales data, property data and assessor's data on all sales.
- Visit each sale on-site, take photographs, make field notes and try to confirm sale with the current property owner.
- Send confirmation requests to those sales not confirm in the field.
- Collect sales and support data from the McLean County Court House.
- Complete sales information data sheets.
- Income stream due to wind turbine lease payments of all sales located within the wind farm.

- The income stream was capitalized and then that amount was extracted from the sales price to leave the vacant land value which was then compared to comparable land sales outside of the wind farm.
- Contract the services of Jim Sanders (appraiser and statistician) with REAL LLC, Tucson, Arizona, to complete the regression analysis and write the summary of the analysis.

The Study

The study utilized a total of 38 agricultural land sales all located within and around the wind farm. Of the total sales, 8 sales were found within the wind farm and 30 were located outside of the wind farm in zones 1-5. The following variables were found and recorded for each sale:

1. Location of sale being either within or outside of the wind farm Zone 0.
2. Sale amount.
3. Date of sale.
4. Acres.
5. Productivity index of the land.
6. Ground cover.

All the sales were selected to have the highest level of comparability to the wind farm land sales. All sales had 100% open ground cover being all open cropland without any wooded areas. The variables of value then became the date of sale and productivity index of the soils.

Study Conclusion

The regression analysis extracted a -8.5% impact on the overall land value due to the presence of the wind farm. Therefore, it is projected that agricultural land located within the wind farm Zone 0 will experience an overall property loss of -8.5% net of the value generated by the wind turbine lease income stream.

Regression Analysis

Regression Analysis: AdjSP versus Productivity, XSDAC, ...

The regression equation is

AdjSP = 2949523 + 10135 Productivity + 10783 XSDAC - 101 Date of Sale - 843 ac zone

Predictor	Coef	SE Coef	T	P	VIF
Constant	2949523	2806081	1.05	0.301	
Productivity	10135	2206	4.59	0.000	1.085
XSDAC	10782.8	148.0	72.83	0.000	1.630
Date of Sale	-101.36	64.15	-1.58	0.124	1.048
ac zone	-843.0	162.3	-5.19	0.000	1.617

S = 65296.1 R-Sq = 99.6% R-Sq (adj) = 99.5%

Analysis of Variance

Source	DF	SS	MS	F	P
Regression	4	3.31308E+13	8.28270E+12	1942.66	0.000
Residual Error	33	1.40698E+11	4263581461		
Total	37	3.32715E+13			

Durbin-Watson statistic = 1.97573

No evidence of lack of fit (P >= 0.1).

This is the XLOF test checking for lack of fit (LOF). This is a test to make sure there are no violations of linearity between the predicted variable of Adjsp and the predicted variables

Explanation of the Predictors

Adjsp: This is the adjusted sales price for those sales located within the wind farm zone that are receiving cash payments. This is the variable that is being predicted in the model. Thus, the sales prices of the farms are being predicted by the variables described below. Note that this model explains 99.5% of the variance in the mean sales price. This is essentially a perfect fit.

Constant: Since the regression analysis is actually multi-linear regression analysis, a straight-line function is estimated. A straight line function takes the form of $y = a + bx_i$, where "y" is the predicted variable, "a" is the constant which represents where the straight line crosses the x-axis in a Cartesian coordinate graph. The "b" represents the coefficients of the explanatory variables.

Productivity: This is a measure of the farm's soil quality stated as crop productivity index (CPI). The coefficient of 10135 means that for every integer increase in the productivity scale results in an increase, on average, of \$10,135 to the sales price. The SE Coef means the standard error of the coefficient which is an indication of variance in this estimate. The "P" value for this coefficient is 0.000 which means a rejection of the null hypothesis that this variable does not impact sales price. To put into practical terms, one CPI unit equals 0.36% increase(decrease) in land value.

XSDAC: This is what is called an interaction variable between SD (sales date) and AC (the number of acres). This variable indicates that on average over time the size of the farms purchased increased. Again, the P value indicates a rejection of the null hypothesis.

Date of Sale: This is the date of sale for each property. Each date is transformed into a number that is created by starting with the first day in January in year 0, assigning the number 1 and increases monotonically with each new day. The -101.36 the negative sign does not mean prices are going down over time because this a correcting adjustment term needed because sales date is part of the interaction variable above.

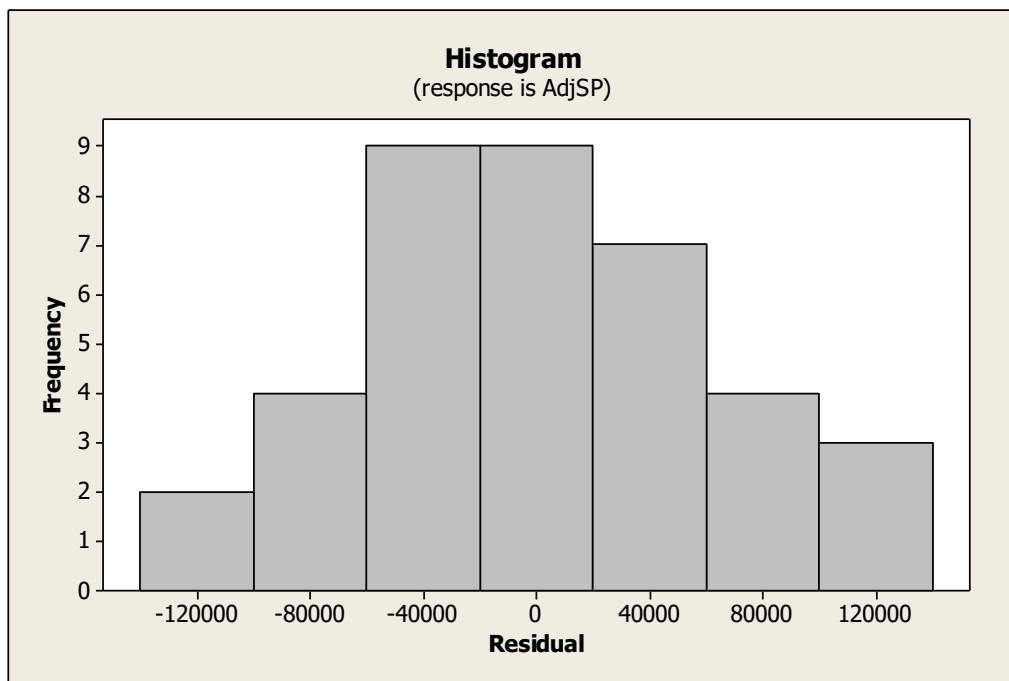

ac zone: This is the variable of interest. This is an interaction term of the number of acres interacting with only those sales located within the wind farm zone. Thus, the -\$843.0 indicates a decrease in value of \$843 per acre on average for the sales located within the wind farm zone. Using the median value of the non-windfarm properties (not adjusted for any variables) of \$9,942 per acre, you have a -8.5% impact due to being within the wind farm.

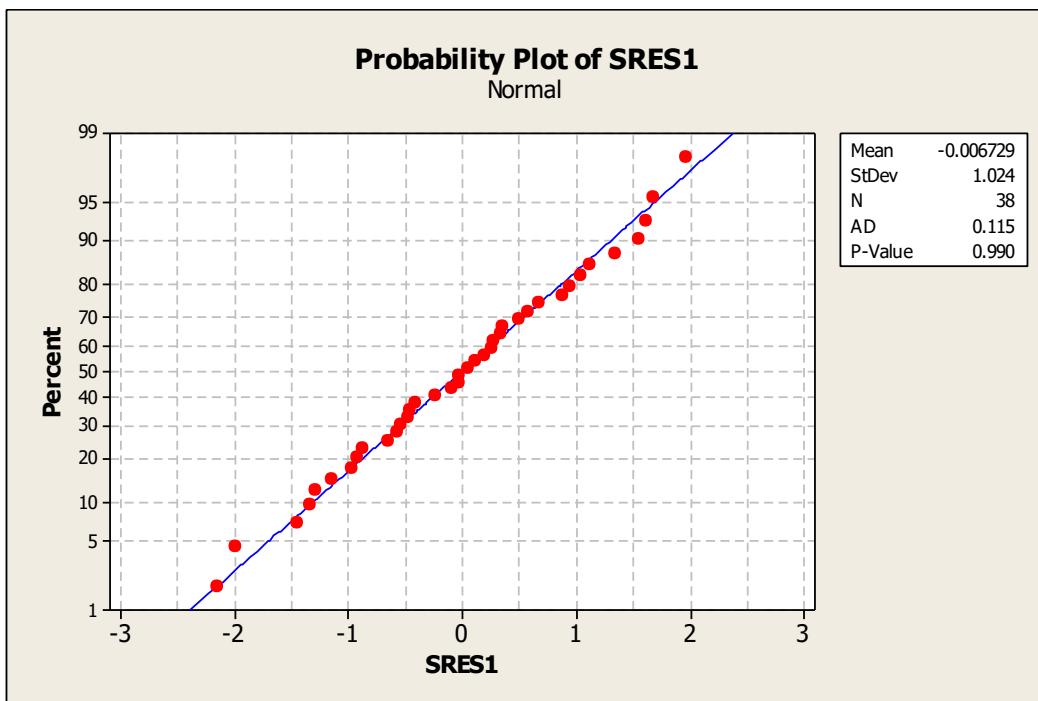

This model was checked to make sure there were no significant violations of the assumptions for regression analysis that are:

1. The regression model is linear in parameters. This means that the relationship between the predicted variable) adjusted sales price) has a linear or straight-line relationship with each predictor variable.
2. The mean of residuals is zero. This means the set actual sales prices for each farm less the model prediction of sales price in normally distributed. This is automatic by how the regression analysis is calculated, that is minimizing the square of this error over the model.
3. Homoscedasticity of residuals or equal variance. This means that the variance of the residuals does not show any patterns that either increases or decreases creating more or less error in the prediction of sales price over the range of each prediction variable. This was tested using the Anderson-Darling test indicating no issues with the distribution of the residuals.
4. No autocorrelation of residuals meaning that the terms in each prediction variable are not correlated with each other. This is tested above by the Durbin-Watson statistic where a score of 2.0 means absolutely no autocorrelation. A perfect score never happens with a real date.

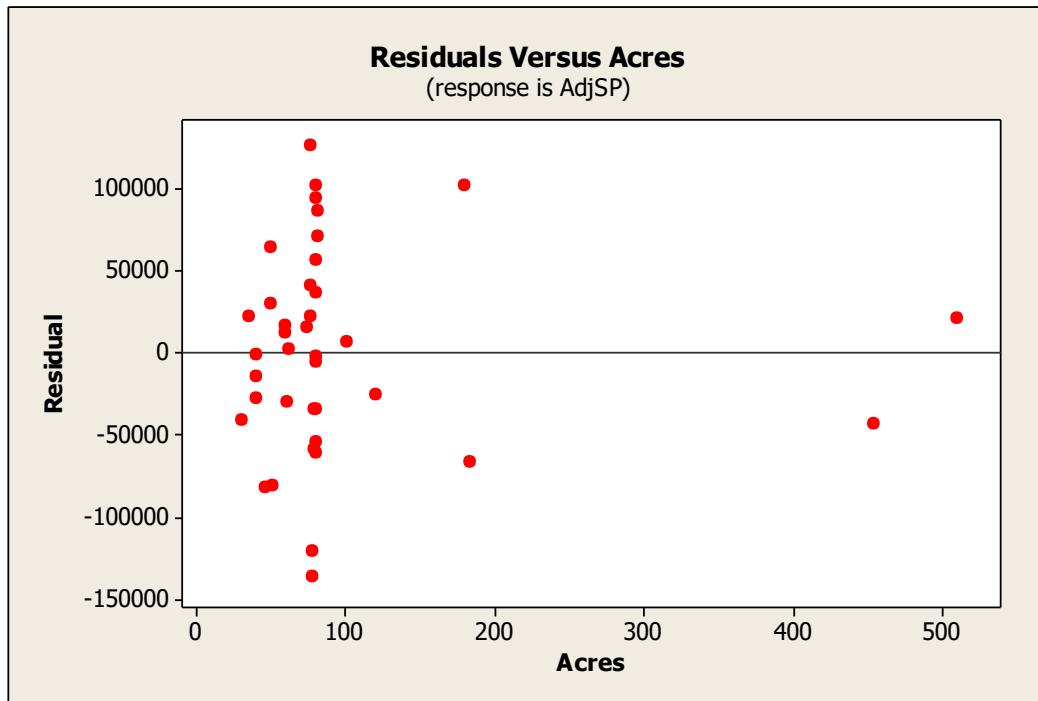

The following pages are some graphics examined looking for issues:

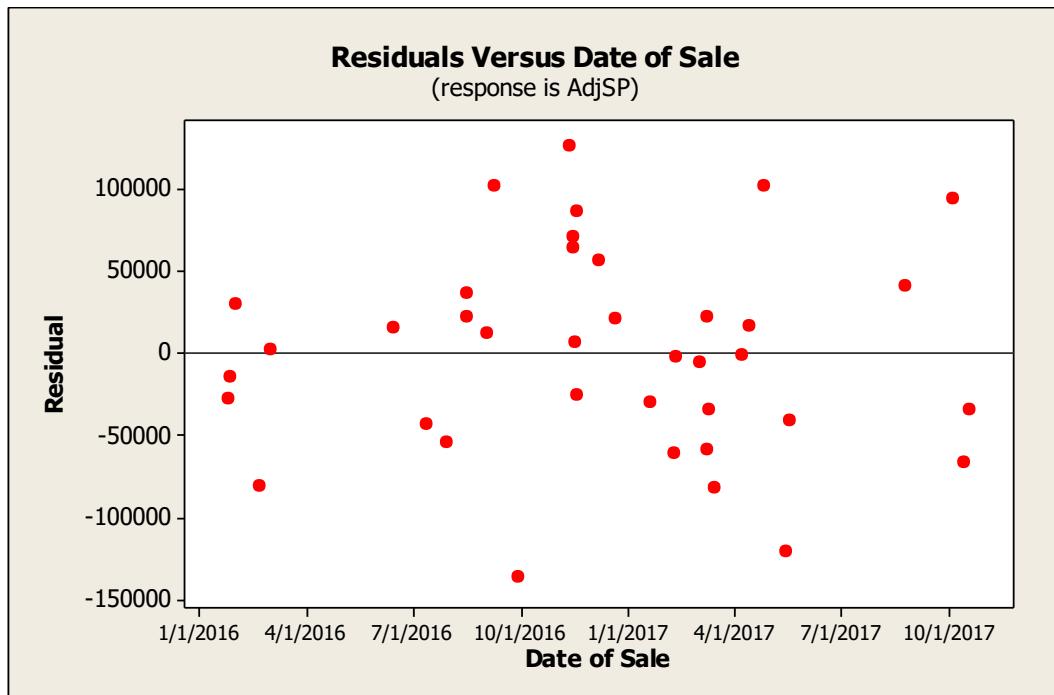

This chart shows a normal distribution of residuals.

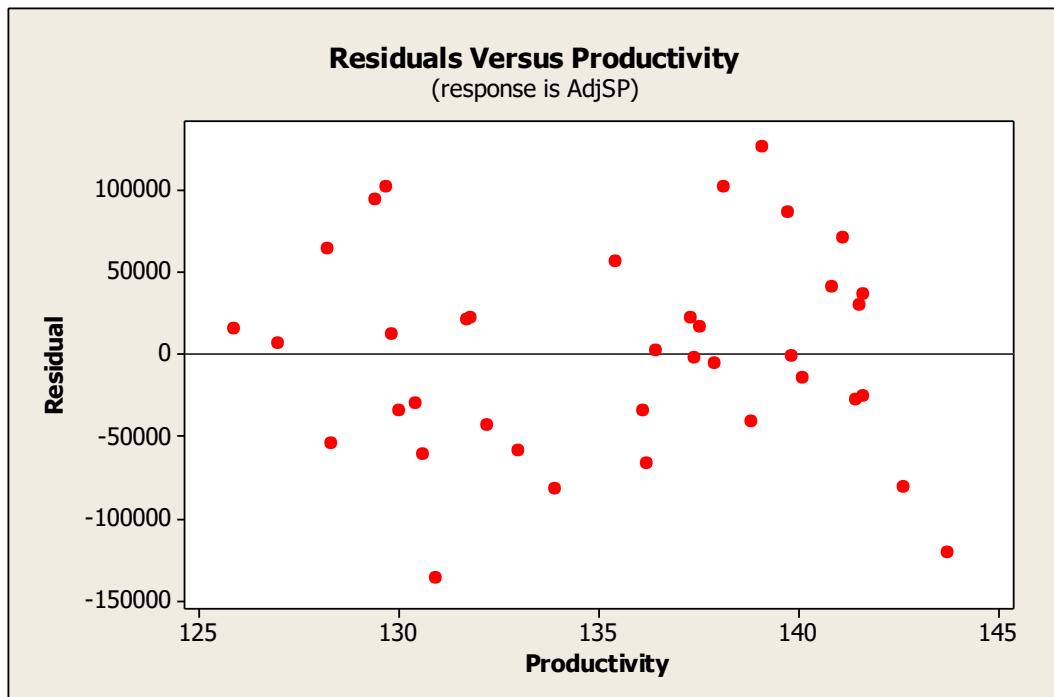

This shows the Anderson-Darling normal probability of the residuals test

This shows the residuals plotted against the number of acres in the dataset. I note that the data has two sales much larger than the rest of the data and two sales larger than the balance of the data. In this model, this is not an issue. In addition, the economics of farm sales and the numerous farm sale data examined over many cases typically show a linear relationship between price per acre and the number of acres where the acres vary from 20 to over 600.

This plot of residuals over time does not indicate any problems. However, it does show that more sales would be needed to have more points in the year 2016.

This last plot of residuals shows no issues.

The following section has the sales data that was used for this analysis.

LAND SALES DATA FOR TWIN GROVES II WIND FARM

Difference before adjustments for time and soil quality

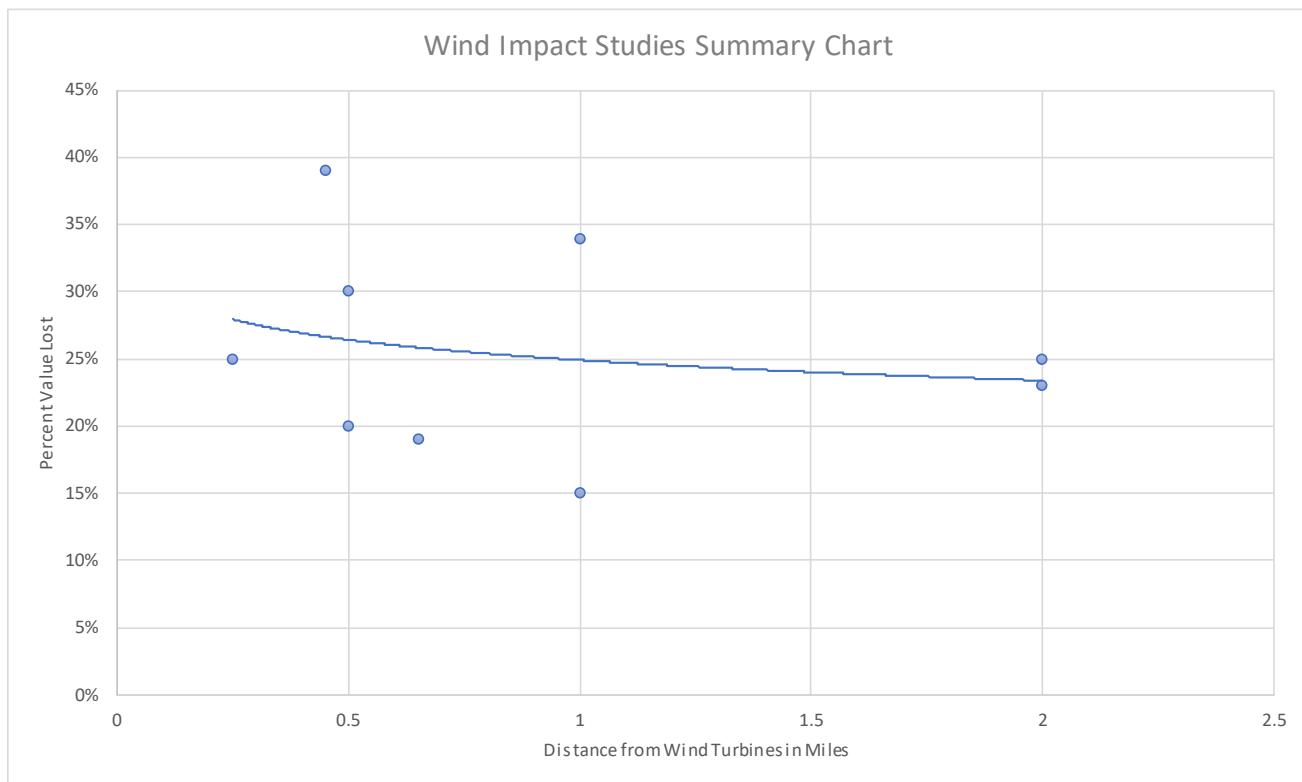

Niyol Wind LLC Property Impact Analysis

Analysis

The literature study answered the question of whether wind farms in proximity to residential homes and agricultural land negatively impact property value with an affirmative. Next, is estimating what that impact would be. To assist in that analysis we will chart out a summary of those studies and their respective impacts by distance from the wind turbines.

Summary of Wind Farm Impact Studies		
study	distance from wind turbine in miles	negative impact to value
Twin Grove II	0.25	25%
Landsink	0.45	39%
AGO Wis	0.5	30%
Twin Grove II	0.5	20%
Big Sky	0.65	19%
Coral Springs	1	34%
Twin Grove II	1	15%
Clarkson University	2	23%
McCann	2	25%

From this chart and graph we have a better understanding on how the distance factor impacts property value. As expected, the closer the wind turbines are to the property the greater the impact.

It should be noted that in all of these studies the wind turbines in place were the older, smaller diameter and of lesser height than what is being proposed for the Niyol wind farm. The Niyol proposal has turbines being 495ft to 505ft in height. This is at least 25% greater in height and breadth than the study turbines. Therefore, it would be logical and reasonable to conclude that this size difference would cause the predictive impacts to be conservative. With that in consideration it would be reasonable to conclude the following impacts:

Properties Within the Wind Farm Footprint

The graph indicates that a -28% loss in value would be found from a distance of 1,500ft from a wind turbine. However, as we noted, those studies used smaller wind turbines. It is estimated that the proposed turbines are at least 25% greater in size. Though a direct correlation of size and impact has not been established, it would be reasonable to estimate the impact would increase by a factor of 1.25. Hence, we conclude the impact to be -35%.

Properties 1-Mile outside of the Wind Farm Footprint

The graph suggests that the impact would be less the further the distance from a wind turbine. The analysis indicates that at 2-mile distance from a turbine the impact would be -18%. Considering that the turbines were smaller in the studies it would be reasonable to increase this impact by a factor of 1.25 to conclude a -22% impact.

Agricultural Properties

Agricultural properties within the footprint, but not participating in the wind lease, will be have a -8.5% impact on property value.

Application to the Loss Estimate

Our client provided us with the residential properties located within the footprint of the Niyol wind farm and those located within 1-mile from the foot print for analysis. They are listed in the following charts along with their assessed value. We will apply the assessed value to the predicted loss to arrive at a total loss estimate due to the Niyol wind farm.

Total assessed value of Border Homes				\$6,948,960

BORDER are homes located 1-mile outside of footprint

Applying the assessed values to the estimated impacts we have the following conclusions:

Niyol Wind Farm Loss to Property Value Estimate			
	total assessed value	impact	value loss
Properties within the Footprint	\$4,014,430	-35%	-\$1,405,051
Properties 1-mile outside of the Footprint	\$6,948,960	-22%	-\$1,528,771
Total			-\$2,933,822

Addendum

Curriculum Vitae of Kurt C. Kielisch

Work Experience

As of January 2020, I have 36 years of experience in the appraisal field. During this tenure I have completed over 8,100 valuations totaling \$13.1+ billion dollars.

As a practitioner, I entered the appraisal industry in 1984 employed by ValuPruf Valuation Service, Milwaukee, Wisconsin. Appraisal assignments through the years have included the following: single-family residential, multi-family residential, dairy farms, crop farms, horse ranches, cattle ranches, commercial properties, special use properties, tax assessment, ocean-front properties and islands, stigmatized properties, eminent domain, utility easements, valuation consulting, litigation support work and impact studies. I have provided appraisal services for properties located in Alaska, Colorado, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Mississippi, Missouri, Nebraska, New Mexico, North Dakota, Ohio, Pennsylvania, South Dakota, South Carolina, Virginia, Wisconsin, and Wyoming.

As a communicator, I have authored the book: *The Listing Appraisal Program* (ATI press, 1996) and three magazine articles: *Dead Body Appraisers* (The Appraisal Buzz, October 3, 2002), *Expert Testimony and Reports: Is Change Good?* (Working R.E. Magazine, February 2002), and *Rails to Trails Property Rights* (Right of Way Magazine, Nov/Dec 2012). I have been engaged in valuation related research projects on the impacts of high voltage transmission lines, natural gas pipelines, oil pipelines, wind farms and solar farms on property value. Related to the impact on property value of utility projects, wind and solar farms, I have given testimony before the Wisconsin Senate Committee, Wisconsin Public Service Commission, Wisconsin Wind Farm Siting Council, Illinois Wind Farm Siting Councils, Missouri Public Service Commission and the Wyoming Industrial Committee. Our research has been utilized by other appraisers, experts and property owners when arguing before government committees, public service counsels, courts and in reports.

As an expert witness, I have been an approved expert in Wisconsin, Kansas, North Dakota, South Dakota and Virginia state courts, commissioner hearings in Wisconsin and Minnesota, mediation in Indiana and Illinois, and Federal Courts in Wisconsin, Kansas and Ohio. In the Wisconsin Supreme Court case of Spiegelberg vs. State of Wisconsin DOT (2004AP3384), I was the principle appraiser for Ms. Spiegelberg. This hearing resulted in a majority decision in favor of my client making a landmark decision relating to the proper valuation methodology when appraising property involved in eminent domain to obtain just compensation. In the Wisconsin Supreme Court decision of Waller vs. American Transmission Corporation, LLC (2012AP805 & 2012AP840) the high court overwhelming found in favor of my client and made a landmark decision involving relocation rights and an uneconomic remnant. I was the principle appraiser and expert witness for the Wallers.

As an educator, I taught appraisal pre-licensing and continuing education courses throughout a multi-state area from 1994 to 2000. During this time, I authored course curriculum for seven pre-licensing courses and twelve continuing education courses as well as the creation of a two-year professional appraiser training program. Since 2000, I have given presentations for professional continuing education (IRWA – Badger Chapter, The American Law Institute and CLE Annual Eminent Domain Conferences (2013, 2014, 2016), IRWA Annual Conference (2013) and for general information at many public meetings.

Academics

M.A. Education. Regent University, Virginia Beach, Virginia. This degree concentrated on the adult learner and state-of-the-art communication technology to enhance learning. The focus was on the adult learner.

B.A. Business Administration (Economics Minor). Lakeland College, Sheboygan, Wisconsin.

B.A. Biology (Natural Sciences Minor). Silver Lake College, Manitowoc, Wisconsin.

EXPLANATION OF DESIGNATIONS

ASA-Urban Real Property: The ASA designation is the senior designation granted by the American Society of Appraisers, which is the only multi-discipline international appraisal association in America. The ASA-Urban designation requires the passing of five advanced level commercial appraisal courses, the passing of a comprehensive exam, a passing grade on a demonstration narrative report, 5 years full-time appraisal experience, a Certified General appraisal license and the recommendation of the local and national membership committee. All ASA designated members must adhere to the Code of Ethics of the Association and keep up-to-date with continuing education (Source: www.appraisers.org).

IFAS (now retired): For this senior level designation from the International Fee Appraisal Association the appraiser must meet the requirements for the Member [IFA], successfully pass the Senior Member Examination, score a passing grade on a narrative demonstration report on an income-producing property conforming to prescribed guidelines and meet educational and experience requirements as outlined by the Association. In addition, the designation requires a minimum of 4 years appraisal experience in commercial type properties, a State Certified General Appraisal license, successful completion of over 200-hours of appraisal course work, completion of the current USPAP course, a college degree and the recommendation of the appraiser's peers and local chapter (Source: www.naifa.com). All IFAS members must adhere to the Code of Ethics of the Association and keep up-to-date with continuing education.

Senior Right of Way (SR/WA): This is the most prestigious professional designation granted by the International Right-of-Way Association to members who have achieved professional status through experience, education, and examination. The SR/WA designation requires training and examination in seven major right-of-way disciplines. The SR/WA designation says, "I have more than five years of right-of-way experience, plus I have had formal training in a wide variety of right-of-way areas." The SR/WA professional may be a specialist in one area such as appraisal, engineering, or law, but also must be familiar with the other seven disciplines associated with the right-of-way profession. Additional requirements for the SR/WA designation include: a bachelor's degree, 5 years right-of-way experience, successful completion of four core courses and four elective courses, passing the all-day comprehensive exam and recommendation from the designee's peers and local chapter. The SR/WA designation is the only designation reflecting evidence of professional attainment in the right-of-way field (Source: www.irwaonline.org). All SR/WA members must adhere to the Code of Ethics of the Association and keep up-to-date with continuing education.

Right of Way Appraisal Certified (R/W-AC): The Right of Way (R/W) Certification is an esteemed professional designation granted to members who have achieved professional status through experience, education, and examination in a specific discipline. Earning this certification demonstrates an unparalleled achievement in a single discipline and reinforces a standard of excellence in services provided to the public (Source: www.irwaonline.org). All R/W-AC members must adhere to the Code of Ethics of the Association and keep up-to-date with continuing education.

Appraiser's Certification

I certify that to the best of my knowledge and belief:

- The statements of fact contained in this report are true and correct.
- The reported analyses, opinions, and conclusions are limited only by the reported assumptions and limiting conditions and are my personal, impartial and unbiased professional analyses, opinions, and conclusions.
- I have no present or prospective interests in the property that is the subject of this report and no personal interest with respect to the parties involved.
- I have no bias with respect to the property that is the subject of this report or to the parties involved with this assignment.
- My engagement in this assignment was not contingent upon developing or reporting predetermined results.
- My compensation for completing this assignment is not contingent upon the development or reporting of a predetermined value or direction in value that favors the cause of the client, the amount of the value opinion, the attainment of a stipulated result or the occurrence of a subsequent event directly related to the intended use of this appraisal.
- My analyses, opinions, and conclusions were developed, and this report has been prepared, in conformity with the Uniform Standards of Professional Appraisal Practice.
- I have made a personal inspection of the property that is the subject of this report.
- No one provided significant real property appraisal assistance other than staff members employed by Forensic Appraisal Group for research and comparable sales confirmation. That individual was Appraisal data technician, Stacy Martin, and staff appraiser James D. Marske.

Signed on June 12, 2020.

Kurt C. Kieliseh, ASA, SR/WA, R/W-AC
President/Senior Appraiser
